## PREFACE

Bangladesh Institute of Nuclear Agriculture (BINA) Annual Research Report 2021-22 would inaugurate a new dimension of research findings exposure. I am certainly delighted to note that this report emphasizing key research outcomes dealing with the use of nuclear and other advance techniques. This report covers several very important sectors of agriculture including food security, livelihood enhancement as well as socio-economic improvement of the country. Many technologies, such as varietal development of cereals (rice and wheat), oilseeds (mustard, rapeseed, groundnut, sesame, soybean and sunflower), pulses (lentil, mungbean, blackgram, chickpea, grasspea, pigeonpea), jute, horticultural crops (fruits, vegetables and spices) have already been found suitable for different agro-ecological zones. Apart from the varietal development attention was also placed on non-commodity fields as soil and water management, crop physiological aspects, cropping systems, plant nutrient pest management, adaptive research and production economics. Emphasis was concentrated on biotechnological research for generating high yielding and climate tolerant crop types and hill farming. This study demonstrates that the scientists of this institute are devoted to create technologies which are appropriate as well as sustainable leading to food and nutritional security of the country. During this period substantial progress was made towards the development of new crop kinds. Five crop varieties were released/registered during this period which were Binamung-11, BINA dhan 25 , BINA soybean, BINA khesari2 and BINA kul1. A total of 497 adaptation trials/block farming using BINA developed crop varieties were undertaken at the farmers' field in partnership with the Department of Agricultural Extension (DAE) and BINA Sub-stations. To motivate farmers and popularize the BINA developed crop varieties/technologies to the end users a total of sixty one farmers training courses were organized during this period and 4000 male and female farmers were trained on cultivation of BINA developed improved crop varieties across the country Besides these, various TV programme were telecasted to market some BINA crop varieties.

I recognize the endeavors that aid with the publication with genuine gratitude to knowledge contribution of deep capacities. This annual report would be highly functional for all scientists, academics, planners, policy makers as well as interested individuals involving agricultural research and development concern in the country and overseas.

## BINA'S OBJECTIVES

- To develop high yielding and better quality crop varieties using both mutation and conventional breeding techniques.
- To assess the fertilizer status of the soils of Bangladesh and efficiency of utilization of applied nutrients by crop plants using radioisotopic techniques.
- To develop means of water use efficiency for optimization of crop yields through radioisotopes and radiation techniques.
- To evolve control measure against major pests and diseases of crop plants.
- To assist national and international research programmes through cooperative support.
- To provide facilities to students of the Bangladesh Agricultural University for carrying out research leading to Masters and Ph.D. degree in Agriculture.
- To arrange training programmes for the research scientists on the peaceful use of atomic energy in agriculture.

## Plant Breeding Division

## Research Highlights, 2021-22

## Rice

One BLB resistant rice line BSB-24 has been selected for T. Aman season having 6.0-6.5 t/ha of grain yield and 115-120 days growth duration. This line has been sent to SCA for field evaluation to be released as a variety. Two rice lines MEF-10 and MEF-27 produced average yield of 6.76 and 6.91 tha $^{-1}$, respectively. These two lines matured within 140 days and suitable for the cultivation in Boro season at Haor areas. Another two rice lines BLB-P-19 and BLB-P-26 produced average yield of 5.76 and 6.15 tha $^{-1}$, respectively. These two lines matured within 110115 days and suitable for the cultivation in T.Aman season. These lines have been sent to SCA for DUS test. Moreover, two high yielding (5.5-6.0 t/ha) Fe and Zn enriched rice lines (IZSD-26 and IZSD-45) with short duration (110-115 days) and red colored pericarp were selected for T . Aman season.

The mutant RM-Kas-80(C)-1 derived from the phosphorus use efficient cultivar Kasalath produced average yield $5.77 \mathrm{tha}^{-1}$ and one mutant RM-16(N)-10 derived from the NERICA-4 produced average yield 6.07 tha $^{-1}$ which was higher than BRRI dhan49 ( 5.30 tha $^{-1}$ ) and both mutants were $8-13$ days earlier than the check variety BRRI dhan 49 . Fifteen lines have been selected of Biroi in $\mathrm{F}_{5}$ generation on the basis of short duration (110-120 days), high yielding (4.5-5.0 t/ha), lodging tolerant characters. Two mutant RM-16(N)-10-1 and RM-16(N)-8-1 selected for Aman season developed by irradiating the seeds of NERICA-4 with N - ion beams whose average yield was 7.2 and 7.7 tha $^{-1}$ and duration was 140-150 days.

## Wheat

1 promising lines was selected for Preliminary Yield Trial (AYT) that is high yielding (3.75-3.80 $\mathrm{t} / \mathrm{ha}$ ) and earliness (114-116 days) especially for Barind area. Twenty lines have been selected for $\mathrm{BC}_{1} \mathrm{~F}_{3}$ generation on the basis of bold seeded, early and high yielding.

## Oil Crop

One soybean variety has been released named as Binasoybean-7 (2.6 t/ha seed yield). One promising mustard mutant (RM005) was selected having low erucic acid ( $26 \%$ ) content. Two advanced lines (RL11 \& RL-17) and four advance mutants (RT-32, RT-35, RT-38 and RT-39) of rapeseed-mustard were selected for further evaluation trial. Twenty-two mutants and sixteen advanced mustard lines from different trials also been selected in respect of maturity period along with some others improved yield components. Two advanced sesame mutants (SM-026 and SM-28) were found promising in respect to higher seed yield and improve agronomic characters. Three promising soybean mutants (SBM-12, SBM-23 and SBM-25) were found in regarding to early maturing period along with higher seed yield. Further selection should be needed for early maturing and high yielding mutants/lines in different generations. Thirty promising sunflower mutants were found regarding to early maturing period along with higher seed yield potential from different generations.

Four promising mutant lines of groundnuts were selected for Advanced yield trial (AYT) on the basis of early and high yielding ( $2.05-2.71 \mathrm{t} / \mathrm{ha}$ ) characters in Rabi season. $7 \mathrm{~F}_{6}$ and $7 \mathrm{~F}_{7}$ lines have been selected for bold seeded, high yielding and 3-4 chambered and high 0/L ratio characters. 50 lines for $\mathrm{F}_{4}$ generation and 30 lines for $\mathrm{F}_{3}$ generation have been selected based on bold seeded, high yielding and 3-4 chambered and high 0/L ratio characters.

## Mungbean

Application will be made to NSB for variety registration of one promising mungbean mutant line (MBM-656-51-2) in respect of earliness, semi synchronous pod maturity, disease tolerant and high yielding. Four (4) putative mungbean mutants were selected on the basis of synchronous habit, early maturity (75-90 days) and high yielding (>1.6 ton/ha).
Lentils: Six mutants were found promising in respect of seed yield and disease reactions. Apart from these lines, five promising mutant lines were selected on the basis of earliness, erect plant type and higher seed yield. In addition, some high yielding early mutants were selected for further evaluation and trials.

Grasspea: Four mutants performed better in respect of seed yield and earliness which were in regional yield trials. Moreover, a good number of advanced mutants were found promising in respect of higher seed yield and earliness.

Blackgram: Application will be made to register a better performed line, BM-105 as a variety, Binamash3 in 2022. In addition, four advanced mutants were selected on the basis of earliness, disease reaction and erect plant type.

## Programme Area: Varietal improvement of cereals Project: Varietal improvement of rice using induced mutation and other advanced breeding techniques

## On-farm and on-station trial of one introgressed bacterial leaf blight resistant rice

Bacterial leaf blight (BLB) of rice caused by Xanthomonas oryzae pv. oryzae (Xoo) is a major pathogen that negatively impacts rice production. BLB causes yield losses generally ranging between 10 and $30 \%$, but which can be as high as $80 \%$, depending on the location, season, weather, crop growth stage and cultivar. The development of a BB-resistant rice cultivar through a gene introgression breeding program is critically important as there are no chemicals or management practices known to reduce the severity of BLB. The present study was conducted to evaluate the yield potential, earliness and BLB resistance of BSB-24, a BLB introgressed rice line at different locations.

This experiment was carried out with a BLB introgressed rice line, BSB-24 with BRRI dhan 49 as a check to assess the yield potential over locations in T. Aman season. Seeds were sown on 318 June 2021 and transplanted during 18 July to 13 August 2021 at different locations. This experiment was conducted at BINA HQ farm, Mymensingh, BINA sub-station farm Ishwardi, Jamalpur, Rangpur and Sunamganj. The experiment followed RCB design with three replications. The size of the unit plot was $4.0 \mathrm{~m} \times 5.0 \mathrm{~m}$. Seedlings were transplanted at a 15 cm distance within rows of 20 cm apart. Recommended doses of nitrogen, phosphorus, potassium, sulphur and zinc were applied in the form of Urea, TSP, MoP, Gypsum and Zinc Sulphate. Cultural and intercultural practices were followed as and when needed. Data on plant height, number of total tillers plant ${ }^{-1}$, effective tillers plant ${ }^{-1}$, panicle length, filled and unfilled grains panicle- ${ }^{1}$ and thousand seed weight were recorded after harvest from 5 randomly selected competitive plants. Maturity was assessed plot basis. Grain yield was recorded from an area of $10 \mathrm{~m}^{2}$ which was later converted to t ha- ${ }^{1}$. Finally, all the recorded data were subjected to proper statistical analyses.

The results obtained from the on-farm and on-station trials of individual locations and mean over locations for all the characters are presented in Table 1. Significant differences were observed between the line and the check variety for yield and yield attributing characters. From mean over locations, it appeared that the BSB-24 line had a significantly higher number of total tiller plant ${ }^{-}$ ${ }^{1}$, effective tillers plant ${ }^{-1}$, thousand grain weight, longer panicle length and grain yield at all the locations than the check variety, BRRI dhan49 (Table 1). There was no significant difference between the test line and check for the number of filled grain and plant height. Highest yield was found at Ishwardi ( $6.99 \mathrm{t} \mathrm{ha}{ }^{-1}$ ) followed by Sunamganj ( $6.15 \mathrm{t} \mathrm{ha}{ }^{-1}$ ), where lowest was at HQ, Mymensingh ( $6.03 \mathrm{t} \mathrm{ha}^{-1}$ ). The higher yield of BSB-24 is attributed by the panicle length and thousand grain weight. Molecular study also identified the BLB resistance genes xa5 and xa13 in BSB-24 derived from a cross between the rice varieties 'Tn-1' and 'IRBB60. This line matured 6-12 days earlier than the check variety BRRI dhan 49 at HQ, Ishwardi, Jamalpur, Rangpur and Sunamganj. Quality assessment was done based on kernel length and L/B ratio. The kernel shape and size of BSB-24 is long-slender where the BRRI dhan49 is medium (Table 2). Based on the yield performance, earliness and resistance against BLB and grain quality, BSB-24 could be selected for further evaluation to release it as a variety.

On farm and on-station trial of two short duration rice lines for better grain quality and higher yield

On-farm and on-station trials were carried out with two lines along with one check variety (BRRI dhan75) at BINA HQ farm Mymensingh and sub-station Magura, Jamalpur, Rangpur and Nalitabari during Aman season of 2021. Seedlings were planted in RCB design with three replications. Unit plot size was $5.0 \mathrm{~m} \times 4.0 \mathrm{~m}$. Plant to plant and row to row distance were 15 cm was 20 cm , respectively. Data on days to flowering, days to maturity, plant height (cm), total number of tillers plant ${ }^{-1}$ number of effective tillers plant ${ }^{-1}$, panicle length $(\mathrm{cm})$, filled and unfilled grains panicle ${ }^{-1}, 1000$ grain weight $(\mathrm{g})$ and grain yield (tha ${ }^{-1}$ ) were recorded from five randomly selected plants of each plot. Plot seed yield was converted to tha ${ }^{-1}$. Recorded data were finally subjected to proper statistical analyses and are presented in Table 3.
The results obtained from the on-farm and on-station trials of individual locations and mean over locations for all the characters are presented in Table 3. Significant differences were observed among the lines and the check variety for yield and yield attributing character. EFSD-58 performed better among the lines and check variety in terms of yield. It produced the highest yield among the lines and the check variety at all the locations (Table 3). Highest yield was found at Rangpur ( $6.24 \mathrm{t} \mathrm{ha}{ }^{-1}$ ) followed by Mymensingh, HQ ( 5.17 tha ). The higher yield of EFSD-58 is attributed by the higher number of effective tillers plant ${ }^{-1}$, number of filled grains panicle ${ }^{-1}$ and panicle length. The duration of this line almost same (101110days) compare to the check variety BRRI dhan75 at all locations and mean over locations. The grain quality parameters data are presented in the Table 4. The lines EFSD-58 and EFSD-21 had the head rice recovery $\% 69.78$ and 66.36 , respectively. The line EFSD-58 had the longest grain ( 6.54 mm ) and the highest $\mathrm{L} / \mathrm{B}$ ratio (3.17) indicating that the line produced medium slender grain (Table 4). Other line and the check variety produced medium slender grain. Based on the yield performance and grain quality EFSD-58 could be selected for further evaluation to release it as a variety.

## On-farm and on-station trial with some iron and zinc rich $M_{10}$ rice mutant

This experiment was carried out to assess overall performance for better grain quality and higher grain yield of four iron and zinc conrtent rice lines along with one check variety Binadhan 20 tested in Aman season during 2022 at BINA HQ's farm Mymensingh, BINA Sub-station Nalitabari, Jamalpur and Cumilla. The experiment followed RCB design with three replications. The size of unit plot was $4.0 \mathrm{~m} \times 5.0 \mathrm{~m}$. Plant to plant distance was 15 cm and row to row distance was 20 cm . Data on days to flowering, days to maturity, plant height $(\mathrm{cm})$, total number of tillers plant ${ }^{-1}$, number of effective tillers plant ${ }^{-1}$, panicle length $(\mathrm{cm})$, filled and unfilled grains panicle ${ }^{-1}$, 1000 grain weight (g) and grain yield (tha ${ }^{-1}$ ) were recorded after harvesting from 5 randomly selected competitive plants/hills. Maturity was assessed plot basis. Recorded data were finally subjected to proper statistical analyses and are presented in Table 5.
It is observed that the results obtained from regional yield trials of individual location and mean over locations for all characters presented in Table 5. Most of the characters showed significant differences among the lines and check for four individual locations and mean over locations. From mean over locations, it appeared that the IZSD-26 line had significantly shorter duration (109 days) and higher number of filled grains (173) at mean over locations than the check variety, Binadhan-20 (Table 5). There was no significant difference between the test line and check for the number of effective tiller and panicle length. Grain yield of this line was significantly higher ( $6.06 \mathrm{t} / \mathrm{ha}$ ) at mean over locations than the check variety Binadhan-20. But the line IZSD-26 and IZSD-45 were matured (109 \& 111 days) earlier than check variety, Binadhan-20 (132 days). As these two lines matured earlier (15-20days) than the check variety Binadhan-20, it would be better to select a desirable check for this trial. The grain quality parameters data are presented in the Table 6 . The highest head rice recovery $\%$ was found in the line IZSD-26 (71.65\%). The line IZSD-26 and check, Binadhan-20 had the head rice recovery $68.80 \%$ and $59.76 \%$, respectively. The check had the longest grain (8.29 mm ) and the highest $\mathrm{L} / \mathrm{B}$ ratio (4.04) indicating that the line produced very long slender grain. Other lines produced long and medium slender grain (Table 6). The mean grain Fe concentration of rice lines ranged from 9 to $15 \mathrm{mg} / \mathrm{kg}$ and 1 to $4 \mathrm{mg} / \mathrm{kg}$ in unpolished \& polished rice, respectively (Figure 1). The mean zinc concentration of rice lines ranged from 45 to $59 \mathrm{mg} / \mathrm{kg}$ and 29 to $40 \mathrm{mg} / \mathrm{kg}$ in unpolished \& polished rice, respectively (Fig. 1). Considering earliness, $\mathrm{Fe}, \mathrm{Zn}$ content and high yields, the lines IZSD-26 could be selected for further evaluation with a suitable check to release it as a variety.

Haor is a term used to describe low-lying areas that are prone to flooding and are submerged in water for several months every year. Haors, which are primarily found in Bangladesh's north-eastern region and are large back swamps or bowl-shaped depressions between the natural embankments of rivers. Although artificial irrigation is occasionally used in this region, natural water is primarily used for rice farming. Longer duration and plant height characteristics of boro rice varieties often become the victim of flash flood. Short duration and high yielding boro rice variety can be blessings for these areas. The objectives of the study were to investigate the evaluation of selected lines over locations.
For this experiment, two lines (MEF-10 \& MEF-27) with the check variety BRRI dhan28 were used during boro season 2021-22 at different locations under the super vision of BINA HQ and BIAN substations. The experiment followed RCB design with three replications. The size of unit plot was $5.0 \mathrm{~m} \times$ 6.0 m . Plant to plant distance was 15 cm and row to row distance was 20 cm . Data on days to flowering, days to maturity, plant height (cm), total number of tillers plant ${ }^{-1}$ number of effective tillers plant ${ }^{-1}$, panicle length (cm), filled and unfilled grains panicle ${ }^{-1}, 1000$-grain weight $(\mathrm{g})$ and grain yield (tha ${ }^{-1}$ ) were recorded after harvesting from 5 randomly selected competitive plants/hills. Maturity was assessed plot basis. The data for the characters under study were statistically analyzed wherever applicable. Data were analyzed using Minitab statistical package.

From the results, significant variations were observed for all the characters at all the locations. Combining mean of over locations, it was observed that MEF-10 \& MEF-27 matured earlier (138.91c \& 140.70b days) than the check variety BRRI dhan28 (146.04a days). MEF-27 produced highest grain yield (6.91a $\mathrm{t} / \mathrm{ha}$ ) followed by MEF-10 (6.76ab t/ha) and BRRI dhan28 ( $6.22 \mathrm{~b} \mathrm{t} / \mathrm{ha}$ ). At farmer's field, early maturity was found in MEF-10 (138.5a days) at Bijoynagar followed by BRRI dhan28 (146.33a days) at mithamoin. Highest yield was found in MEF-10 (7.3a t/ha) at Bijoynagar farmer's field followed by BRRI dhan28 ( 5.87 b t/ha) a5.87b t/ha. Among different BINA stations, MEF-27 produced highest grain yield and filled grain (7.47a t/ha \& 144.66a) at BINA sub-station Cumilla and MEF-10 (7.28a, 126.66a) at BINA HQ farm, Mymensingh (Table 7). In our country flash flood usually comes at haor areas from the 1st week of April to 2nd week. It causes huge loss of Boro crop at haor areas. As both of the lines are mature 6-7 days earlier than the check variety BRRI dhan 28 , it could escape early flash flood at haor areas. Considering short duration and higher yield, further evaluation will be done for these lines (MEF10 \& MEF-27).

Recent years, flash floods were a frequent occurrence that caused rice cultivation in the haor areas to be disrupted, have led to reduced yields of rice production in the Boro season. The study concludes that, cultivation of MEF-10 and MEF-27 lines in proper time can be economically more viable in the haor areas.

## On-farm and on-station yield trial of rice lines for earliness and higher grain yield

Due to the significance impact of rice in ensuring national food security and income for those with low incomes, achieving self-reliance in rice production and maintaining price stability are significant goals in low-income countries. Developing short duration rice cultivars is considered to be one of the most effective and economic approaches for ensuring food security particularly in northern part of the country. Farmer's of these region can better face the manga problem during "karthik" (Oct-Nov) by cultivating this line in proper time. The objectives of the study were to investigate the evaluation the yield potential of the selected line over locations.

For this experiment, line MEF-12 with the check variety BRRI dhan75 were used during Aman season 2021-22 at different locations under the super vision of BINA HQ and different BINA sub-stations. The experiment was followed RCB design with three replications. The size of unit plot was $5.0 \mathrm{~m} \times 6.0 \mathrm{~m}$. Plant to plant distance was 15 cm and row to row distance was 20 cm . Data on days to flowering, days to maturity, plant height (cm), total number of tillers plant ${ }^{-1}$ number of effective tillers plant ${ }^{-1}$, panicle length $(\mathrm{cm})$, filled and unfilled grains panicle ${ }^{-1}, 1000$-grain weight ( g ) and grain yield (tha ${ }^{-1}$ ) were recorded after harvesting from 5 randomly selected competitive plants/hills. Maturity was assessed plot basis. The data for the characters under study were statistically analyzed wherever applicable. Data were analyzed using Minitab statistical package.

Significant variations were observed among the lines and check varieties for most of the characters in both of individual location and combined over locations. Results from combined mean of over locations, it was revealed that MEF-12 matured earlier (110.9 days) than the check variety BRRI dhan75 (115.04 days). Again, MEF-12 produced higher grain yield ( $5.24 \mathrm{t} / \mathrm{ha}$ ) than BRRI dhan75 (4.91b t/ha). Highest number of total tillers plant ${ }^{-1}$ and number of effective tillers plant ${ }^{-1}$ were observed in the line MEF-12 followed by check variety BRRI dhan75. Highest grain yield was found in MEF-12 (5.39 t/ha) at BINA HQ farm, Mymensingh and lowest was found at BINA sub-station Ishwardi of BRRI dhan75 (4.87b t/ha) (Table 8).

Rice varieties that may mature early without significantly affecting production are needed due to both the crop intensification and climate change. According to reports, one method of reducing the emissions of the greenhouse gases methane and nitrous oxide is to employ short-duration rice cultivars. To sum up, further evaluation of the line MEF-12 can be helpful to release as short duration Aman rice variety.

## Regional yield trial of introgressed bacterial leaf blight resistant rice lines at Aman season

This experiment was carried out to assess high yield attributes of two BLB resistant rice lines along with two check varieties BRRI dhan75 tested in Aman season during 2021 at BINA HQ's farm, Mymensingh and BINA Sub-station Rangpur and Nalitabari. The size of unit plot was $4.0 \mathrm{~m} \times 3.0 \mathrm{~m}$. Plant to plant distance was 15 cm and row to row distance was 20 cm . Data on days to flowering, days to maturity, plant height (cm), total number of tillers plant ${ }^{-1}$ number of effective tillers plant ${ }^{-1}$, panicle length (cm), filled and unfilled grains panicle ${ }^{-1}$, 1000 grain weight ( g ) and grain yield (tha ${ }^{-1}$ ) were recorded after harvesting from 5 randomly selected competitive plants/hills. Maturity was assessed by plot basis. Recorded data were finally subjected to proper statistical analyses and are presented in Table 3.
The results obtained from Regional yield trials of individual location and mean over locations for all characters are presented in Table 9. Most of the characters showed significant differences among the lines and check for three individual locations and mean over locations. In respect of yield, BLB-P-26 produced the highest yield ( $6.01 \mathrm{t} / \mathrm{ha}$ ) followed by BLB-P-19 ( $5.79 \mathrm{t} / \mathrm{ha}$ ). This higher yield is contributed by the higher number of filled grains panicle ${ }^{-1}$ than the check variety at all the locations (Table 9). It also produced the higher thousand grain weight and panicle length than check the check variety at from mean over locations. There was no significant difference between the test line and check for the number of total tiller, effective tiller and days to maturity. These lines were found resistant to BLB while check showed susceptible in visual observation at all locations. Quality assessment was done based on kernel length and L/B ratio. The kernel shape and size of BLB-P-19 and BLB-P-26 was long-slender and medium-slender where the BRRI dhan75 was medium (Table 10). Considering BLB resistance and high yield the lines BLB-P-19 and BLB-P-26 will be evaluated for on-farm and on-station yield trial in next Aman season.

## Regional yield trial of introgressed bacterial leaf blight resistant rice lines at Boro season

This experiment was carried out to assess high yield attributes of three BLB resistant rice lines along with one check variety BRRI dhan28 tested in Boro season during 2021-22 at BINA HQ's farm, Mymensingh and BINA Sub-station Ishwardi, Sunamgonj, Nalitabari and farmers field of Netrokona and Kishargonj, The size of unit plot was $4.0 \mathrm{~m} \times 3.0 \mathrm{~m}$. Plant to plant distance was 15 cm and row to row distance was 20 cm . Data on days to flowering, days to maturity, plant height (cm), total number of tillers plant ${ }^{-1}$ number of effective tillers plant ${ }^{-1}$, panicle length ( cm ), filled and unfilled grains panicsle ${ }^{-1}, 1000$ grain weight (g) and grain yield (tha ${ }^{-1}$ ) were recorded after harvesting from 5 randomly selected competitive plants/hills. Maturity was assessed by plot basis. Recorded data were finally subjected to proper statistical analyses and are presented in Table 11.

The results revealed from Regional yield trials of individual location and mean over locations for all the characters are presented in Table 11. Results mean over three locations, on an average, all other characters showed significant differences among the lines and check for both individual locations and mean over locations. Among the lines and check varieties, BLB-P-42 had the longest plant height at all the locations (Table 11). Highest number of total tillers plant ${ }^{-1}$ and number of effective tillers plant ${ }^{-1}$ were observed at almost all the locations by line BLB-P-42 but except at Mymensingh by BLB-P-44. BLB-P-48 had the longest panicle and BLB-P-42 had the highest number of filled grains panicle ${ }^{-1}$ at almost all the locations (Table 4). BLB-P-42 produced the highest yield at almost all the locations except Ishwardi by BLB-P-44. BLB-P-42 (7.59 tha ${ }^{-1}$ ) and BLB-P-44 (7.11tha ${ }^{-1}$ ) produced significantly highest yield at mean over three locations than the check variety ( 6.22 tha $^{-1}$ ). BLB-P-44 (143 days) matured 10 days earlier than the all lines and check variety but BLB-P42 had almost same duration with check BRRIdhan58. BLB-P-42 had the lowest thousand grain weight ( 21.38 g ) which indicate fine grain quality. Quality assessment was done based on kernel length and L/B ratio. The kernel shape and size of BLB-P-42 was long-slender and BLB-P-44, BLB-P-48 was medium-slender where the BRRI dhan58 was medium (Table 12). Based on the yield performance and grain quality, BLB-P-42 are suggested for on-farm and on-station yield trial in next Boro season.

## Regional yield trial of rice lines for better grain quality and higher yield

For smallholder farmers, securing a high and reliable income from farming despite rising cultivation costs is a regular difficulty. Premium quality rice varieties have a $20-60$ percent price advantage and 50 percent higher profit over other rice varieties, indicating that there could be significant interest in expanded production. The objectives of the study were to investigate the selected rice lines with premium quality.

For this experiment, three rice lines (MPQR-62, MPQR-72 \& MPQR-81) with the check variety BRRI dhan49 were used during Aman season 2021-22 at different locations (BINA HQ, Mymensingh, BINA sub-station farm Nalitabari \& Ishwardi). The experiment was followed RCB design with three replications. The size of unit plot was $5.0 \mathrm{~m} \times 4.0 \mathrm{~m}$. Plant to plant distance was 15 cm and row to row distance was 20 cm . Data on days to flowering, days to maturity, plant height ( cm ), total number of tillers plant ${ }^{-1}$ number of effective tillers plant ${ }^{-1}$, panicle length ( cm ), filled and unfilled grains panicle ${ }^{-1}$, 1000grain weight (g) and grain yield (tha ${ }^{-1}$ ) were recorded after harvesting from 5 randomly selected competitive plants/hills. Maturity was assessed plot basis. The data for the characters under study were statistically analyzed wherever applicable. Data were analyzed using Minitab statistical package.

Significant variations were observed among the lines and check varieties for most of the characters in both of individual location and combined over locations. From the table it was observed that, MEF-72 matured early ( 130.55 c ) than others. Comparing with the check variety BRRI dhan 49 , plant height of MEF-62 and MEF-72 were 104.75 cm and 104.68 bcm respectively. Effective tiller (10.35a) was found in MEF-62 in compare with the check variety BRRI dhan49 (9.23). Although MEF-62 (4.83 tha ${ }^{-1}$ ) has lower grain yield than BRRI dhan49 (5.03 tha ${ }^{-1}$ ). Less 1000-grain weight (g) in MEF-62 ( 22.35 g ) against the check variety BRRI dhan-49 (23.40a ) proved that the line has premium quality rice grain (Table 13).

Cultivation of fine grain rice has been gaining popularity in Bangladesh over the recent years, because of its huge demand both for internal consumption and export. The line MPQR-62 having slender grain with pleasant yield will be evaluated furthermore.

## Regional yield trial with some heavy ion beams irradiated mutants derived from Kasalath and NERICA-10

Kasalath, a traditional rice variety, is grown in Sylhet region and in parts of north-eastern India, and IRRI has recently developed some varieties from Kasalath, which could increase rice production by $25 \%$. Kasalath is infused with "phosphorus Starvation Tolerance" gene called PSTOL-1. The gene has potentials to enable rice plants to produce $25 \%$ more grain by increasing uptake of phosphorus at limited plant nutrient. NERICA-10 is a variety of Africa has a good tolerance against blast, Moderate tolerance to lodging. Meanwhile, Sterility is the main problem of NERICA-10 that hinders to obtain optimum yield. Kasalath and NERICA-10 was irradiated to develop early, high yielding and fine grain rice lines over the parents.

Seeds of one $\mathrm{M}_{10}$ mutant of Kasalath (derived from the irradiation by 80 Gy carbon ion beams) and two $\mathrm{M}_{6}$ mutants viz. RM-16(N)-8 and RM-16(N)-10 of rice (derived from nitrogen ion beams) were sown at five locations during 07 to 15 July 2021 and seedlings were transplanted during 31 July to 29 August 2021 along with a check variety BRRI dhan 49 presented in Table 1. Plant to plant and row to row distance were maintained 15 cm and 20 cm respectively. The experiment was followed by Randomized Complete Block Design (RCBD) with three replications. The size of the unit plots were $4 \mathrm{~m} \times 5 \mathrm{~m}$. Recommended doses of nitrogen, phosphorus, potassium, sulphur and zinc were applied in the form of Urea, TSP, MoP, Gypsum and Zinc Sulphate. Cultural and intercultural practices were followed as and when necessitated. Data on plant height, number of effective tillers plant ${ }^{-1}$, panicle length, and filled and unfilled grains panicle ${ }^{-1}$ were recorded after harvest from 5 randomly selected competitive plants. Maturity was assessed plot basis. Grain yield was recorded from an area of $10 \mathrm{~m}^{2}$ which was later converted to $t a^{-1}$. Finally, all the recorded data were analyzed statistically as per design and are presented in Table 14.

Significant variation among the mutants and the check for most of the characters were showed in combined and individual locations. In combined locations, it was observed that the mutant RM-Kas-80(C)-1 had statistically higher plant height ( 123.49 cm ) comparing to the mutants RM-$16(\mathrm{~N})-8(96.29 \mathrm{~cm})$, RM-16(N)-10 ( 94.48 cm ) and the check variety BRRI dhan49 ( 105.87 cm ) (Table 16). Panicle length was highest in RM-Kas-80(c)-1 mutant ( 26.91 cm ) comparing to the check variety BRRI dhan49 ( 22.77 cm ). The mutants RM-16(N)-8, RM-16(N)-10 represented statistically higher effective tillers (10.40, 9.66 respectively) comparing to the check variety BRRI dhan49 (9.28). Highest number of filled grain was observed in check variety BRRI dhan 49 (140.58) comparing to the RM-16(N)-8 (102.89), RM-16(N)-10 (105.99) and Kas-80(c)-1 (134.51). Statistically significant variation was found in yield for three mutants. Mutants RM-Kas-80(C)-1 RM-16(N)-10 produced higher yield ( $5.77 \mathrm{t} / \mathrm{ha}$ ) and ( $6.07 \mathrm{t} / \mathrm{ha}$ ) than the check variety BRRI dhan49 ( $5.30 \mathrm{t} / \mathrm{ha}$ ).Considering the yield performance of the mutant RM-Kas-80(C)-1 and RM-16(N)-10 will be put into the next trail for next Aman season (Table 16). Duration of the mutants RM-Kas-80(C)-1, RM-16(N)-8-1 and RM-16(N)-10-1 ranges from 121129 days, 122-127 days and 127-131 respectively whereas the duration of the check variety BRRI dhan49 varies from 135-140 days. The mutant RM-Kas-80(C)-1 was 14 days earlier than
the check variety BRRI dhan49 (Table 15) whereas the mutant RM-16(N)-8-1 and RM-16(N)-81 are 8-13 days earlier contrasting to the check variety BRRI dhan49 (Table 15 and Table 16).

In a column, values with same letter (s) for individual location/ combined means do not differ significantly at 5\% level

Considering the yield \& yield attributes, the promising line RM-16(N)-10 and RM-Kas-80(C)-1 will be evaluated for the next trial.

## Regional yield trial with two high yielding $M_{7}$ NIRICA mutants

A minimum of an average rice yield target of 9.1 ton/ha has been roughly set for 2050. However, this target cannot be achieved equally across all the geographic regions of Bangladesh. Because,
the country has various 'rice types' based on specific ecosystems, and also due to the pressing 'needs'. All these 'rice types' have different situation-specific yield potentials and area coverage. The breeding objective was to develop a high yielding rice variety for boro season that will achieve the future target of genetic yield potential (GYP) in Bangladesh

Two promising $\mathrm{M}_{7}$ mutants [RM-16(N)-8-1 and RM-16(N)-10-1] of rice derived from heavy ion (nitrogen) beam irradiation were evaluated at eight locations, six at different stations and two at farmer's field. This trial was carried out with the objectives of high temperature tolerant, short duration, high yielding with non shattering grains as well as to assess the yield potential over locations. Seeds were sown during 25 November to 09 December, 2021 and transplanted during 5 January to 6 February 2021 (Table 17). The experiment was conducted by following RCB design with three replications. The size of the unit plots were $4 \mathrm{~m} \times 5 \mathrm{~m}$. Plant to plant distance was 15 cm and row to row distance was 20 cm . Recommended doses of nitrogen, phosphorus, potassium, sulphur and zinc were applied in the form of Urea, TSP, MoP, Gypsum and Zinc Sulphate. Cultural and intercultural practices were followed as and when necessitated. Data on plant height, number of effective tillers hill ${ }^{-1}$, panicle length and number of filled and unfilled grains panicle ${ }^{-1}$ were recorded after harvesting from five randomly selected competitive hills. Days to $50 \%$ of flowering, Days to maturity was assessed on plot basis. Grain yield was recorded from an area of $10.0 \mathrm{~m}^{2}$ which was later converted into tha ${ }^{-1}$. Finally, all the recorded data were subjected to proper statistical analyses and are presented in Table 19.

Results showed significant variation among the mutants and check for most of the characters in individual and over locations in combined analysis. From combined analysis, it was observed that plant height of two mutants lines RM-16(N)-8-1 and RM-16(N)-10-1 were 93.80 cm and 93.69 cm respectively and which were statistically shorter than the check variety BRRI dhan 58 (109.08cm). RM-16(N)-8-1 and RM-16(N)-10-1 had statistically higher number of effective tillers (14.53 and 13.70 respectively) comparing to BRRI dhan58 (11.76). Panicle length of RM-$16(\mathrm{~N})-8-1$ and $\mathrm{RM}-16(\mathrm{~N})-10-1$ were recorded as 23.79 and 25.03 cm respectively. The highest number of filled grain panicle ${ }^{-1}$ were observed in RM-16(N)-10-1 (101.97) and RM-16(N)-8-1 (115.99) followed by BRRI dhan58 (123.15). BRRI dhan58 had statistically maximum number of unfilled grain panicle ${ }^{-1}$ contrasting to RM-16(N)-10-1 and RM-16(N)-8-1 mutants. The mutants RM-16(N)-8-1 and RM-16(N)-10-1 had produced higher yield (7.2 \& 7.6 tha $^{-1}$ respectively) than the BRRI dhan58 (7.1) (Table 19). Duration of the mutants RM-16(N)-8-1, RM-16(N)-10-1 ranges from 140-145 days and 145-150 days respectively whereas the duration of the check variety BRRI dhan58 varies from 144-150 days. The mutant RM-16(N)-8-1 was 4 days earlier than the check variety BRRI dhan58 (Table 18) whereas the mutant RM-16(N)-10-1 had similar duration but gave higher yield contrasting to the check variety BRRI dhan58 (Table 18 and Table 19).

In a column, values with same letter (s) for individual location/ combined means do not differ significantly at 5\% level
Considering the Duration, yield \& yield attributes of the mutants RM-16(N)-10-1 and RM-$16(\mathrm{~N})-8-1$ will be evaluated in the next trail to release as a variety

## Advance yield trial of Brown Plant Hopper (BPH) resistant rice lines

Numerous biotic and abiotic factors have a negative effect on rice productivity. Every year, biotic factors cause damage to about 52 percent of the world's rice production, with insect pest attacks accounting for nearly 21 percent of that loss. BPH can consume more than $28 \%$ of the dry matter of infected rice plants at the reproductive stage and also it can transmit various viral diseases. For controlling BPH damage, selection of BPH resistant line is the main objective of this research.

For this experiment, six rice lines with the check variety BRRI dhan96 were used during Boro season 2021-22 at different locations (BINA HQ, Mymensingh, BINA sub-station farm Rangpur \& Ishwardi). The experiment was followed RCB design with three replications. The size of unit plot was $5.0 \mathrm{~m} \times 4.0$ m . Plant to plant distance was 15 cm and row to row distance was 20 cm . Data on days to flowering, days to maturity, plant height $(\mathrm{cm})$, total number of tillers plant ${ }^{-1}$ number of effective tillers plant-1, panicle length ( cm ), filled and unfilled grains panicle ${ }^{-1}$, 1000 -grain weight ( g ) and grain yield (tha ${ }^{-1}$ ) were recorded after harvesting from 5 randomly selected competitive plants/hills. Maturity was assessed plot basis. The data for the characters under study were statistically analyzed wherever applicable. Data were analyzed using Minitab statistical package.

From the results, significant variations were observed for all the characters at all the locations. Combining mean of over locations, it was observed that BRRI dhan96 matured earlier ( 140.22 days) than the other lines. BPH-P-065 produced highest grain yield (7.62a t/ha) followed by BPH-P-034 (7.58 t/ha) and BPH-P-043 (7.53 t/ha). Highest Filled grain was also found in BPH-P-065 (135.78) that also has highest 1000 grain weight (26.23a ) in mean of over locations. But BPH-P-034 showed highest 1000 grain weight in three locations, individually. Early maturity was found in BPH-P-009 around 139 days followed by check variety BRRI dhan96 (around 140 days) at BINA HQ's farm, BINA sub-station farm Rangpur, and Ishwardi and also in mean of over locations. Highest number of effective tillers was produced by BPH-P065 (14.56) in mean of over locations and also at BINA HQ's farm and BINA sub-station farm Rangpur, \& Ishwardi (Table 20). According to BPH scoring (Standard protocol by IRRI), BPH-P-065 has very slight damage whereas BPH-P-34, BPH-P-43 and BRRI dhan96 showed that, $1^{\text {st }} \& 2^{\text {nd }}$ leaves of most plants partially yellowing. As BPH-P-065, BPH-P-034 and BPH-P-043 showed better performance in term of grain yield and other yield contributing characters (Table 21).

To recapitulate, rice lines BPH-P-34, BPH-P-43 \& BPH-P-65 performed better than other lines in terms of yield and other characters as well as BPH score. Further evaluation of these lines will be made to release as BPH resistance rice variety.

Table 21: BPH scoring based on IRRI standard

| Scale |  | Line(s) Name | Damage |
| :--- | :--- | :--- | :--- |
| HT/HR | 0 | - | None |
| T/R | 1 | BPH-P-065 | Very slight damage |
| MT/MR | 3 | BPH-P-034, BPH-P-043, BRRI dhan96 | $1^{\text {st } \& 2^{\text {nd }} \text { leaves of most plants partially yellowing }}$ |
| MS | 5 | BPH-P-009, BPH-P-020 | Half of plants wilting or dead |
| S | 7 | BPH-P-057 | More than half of plants wilting or dead |
| HS | 9 | - | All plants dead |

HT/HR- High tolerant/ resistant, T/R- Tolerant/resistant, MT/MR- Moderately tolerant/resistant, MSModerately susceptible, S-Susceptible, HS-Highly susceptible

## Advanced yield trial of blast resistant rice lines in Boro season

This experiment was carried out to assess the yield and yield attributes of three blast resistant rice lines along with one check variety BRRI dhan58 tested in Boro season during 2021-22 at BINA HQ's farm, Mymensingh and BINA Sub-station farm Rangpur, Comilla, Magura \& Jamalpur. Seeds were sown on $20^{\text {th }}$ November 2021 and transplanted to the field on 22 December 2021. The experiment followed RCB design with three replications. The size of unit plot was $2.0 \mathrm{~m} \times 1.0 \mathrm{~m}$. Plant to plant distance was 15 cm and row to row distance was 20 cm . Recommended doses of nitrogen, phosphorus, potassium, sulphur and zinc were applied in the form of Urea, TSP, MoP, Gypsum and Zinc Sulphate. Cultural and intercultural practices were followed as and when necessitated. Data on days to maturity, plant height ( cm ), total number of tillers plant ${ }^{-1}$, number of effective tillers plant ${ }^{-1}$, panicle length (cm), filled and unfilled grains panicle ${ }^{-1}$ and 1000-grain weight (g) were recorded after harvesting from 5 randomly selected competitive plants/hills. Maturity and yield data were recorded plot basis. Finally, the yield data were converted to $\mathrm{t} \mathrm{ha}{ }^{-1}$. Recorded data were finally subjected to proper statistical analyses. The results revealed from advanced yield trials of individual location and mean over locations for all the characters are presented in Table 22. Results mean over three locations, on an average, all other characters showed significant differences among the lines and check for both individual locations and mean over locations. Among the lines and check varieties, BRRI dhan58 had the longest plant height at all the locations. Highest number of total tillers plant ${ }^{-1}$ and number of effective tillers plant ${ }^{-1}$ were observed at Mymensingh and Rangpur by line BN-P-318 at Jamalpur and Magura by BN-P-120 and at Comilla by BN-P-317. BN-P-317 had the longest panicle at 3 locations Mymensingh, Magura \& Jamalpur (Table 22). Highest number of filled grains panicle ${ }^{-1}$ was observed at Comilla by BN-P-318 (147.53). BN-P-318 and BN-P-317 produced the highest yield at all five locations, respectively. BN-P- 317 and BN-P-318 produced significantly highest yield at mean over five locations. Based on the yield performance, BN-P-318 and BN-P-317 are suggested for regional yield trial in next Boro season.

## Advance yield trial of Blast Nursery Rice Lines (IRBN) in Aman season

This experiment was conducted to select desirable lines having Blast resistance, higher grain yield, short duration suitable for Aman season. Six IRBN rice lines along with two check varieties Binadhan-7 and Binadhan-17 tested in Aman season of 2021 at BINA Headquarter farm, Mymensingh and BINA Substation, Cumilla. Seeds were sown on 11 July 2021 and transplanted to the field on 8th August 2021 at Mymensingh and Cumilla. The experiment was laid out in RCBD with three replications. Unit plot size was 2 mx 3 m and spacing between hills and rows were 15 cm and 20 cm , respectively. Data on plant height (cm), effective tillers hill${ }^{1}$ (no.), number of filled grains penicle ${ }^{-1}$ and panicle length (cm) were recorded from five randomly selected plants from each plot. Days to fifty \% flowering and days to maturity were assessed by plot basis. Grain yield data were recorded from an area of $6.0 \mathrm{~m}^{2}$. Finally, all the recorded data were subjected to proper statistical analyses and are presented in Table 23

Table 23 Mean performance of IRBBN rice lines along with check varieties during Aman season 2021

From the table 23, Days to maturity of IRBBN-31 and IRBBN-9 was the longest and the check varieties took shortest time to mature at both location. All the lines produced taller plant than check varieties. Shortest plant height was found in check variety Binadhan-17 and it was similar with Binadhan-7. There was no significant difference in combined effect of effective tillers per plant in Mymensingh among the lines and check varieties. Binadhan-7 produced highest number of effective tillers at Cumilla and it was similar with other check variety and line IRBBN-9. All lines had produced taller panicle length than check varieties and IRBBN-9 had produced taller panicle length. IRBBN-17, IRBBN-18, IRBBN-31 and check variety Binadhan-17 had produced highest numbers of filled grains panicle ${ }^{-1}$. The check variety Binadhan- 17 had produced highest yield than other lines and check variety. This experiment with these lines will be repeated for further evaluation in next year.

## Advance yield trial of Blast Nursery Rice Lines (IRBN) in Aman season

This experiment was conducted to select desirable lines having Blast resistance, higher grain yield, short duration suitable for Aman season. Six IRBN rice lines along with two check varieties Binadhan-7 and Binadhan-17 tested in Aman season of 2021 at BINA Headquarter farm, Mymensingh and BINA Substation, Cumilla. Seeds were sown on 11 July 2021 and transplanted to the field on 8th August 2021 at Mymensingh and Cumilla. The experiment was laid out in RCBD with tthree replications. Unit plot size was $2 \mathrm{mx} \mathrm{3m}$ and spacing between hills and rows were 15 cm and 20 cm , respectively. Data on plant height ( cm ), effective tillers hill${ }^{1}$ (no.), number of filled grains penicle ${ }^{-1}$ and panicle length (cm) were recorded from five randomly selected plants from each plot. Days to fifty \% flowering and days to maturity were assessed by plot basis. Grain yield data were recorded from an area of $6.0 \mathrm{~m}^{2}$. Finally, all the recorded data were subjected to proper statistical analyses and are presented in Table 24

Table 24 Mean performance of IRBN rice lines along with check varieties during Aman season 2021

| IRBN-18 | 59 ab | 128b | 114.17a | 6.44 b | 29.08a | 147.78a | 38.56c | 3.23a | 22.39b |
| IRBN-25 | 54d | 123.5c | 92.61c | 6.86 b | 26.42c | 113.68bc | 41.22 cd | 3.41a | 21.19e |
| Binadhan-7 | 56.6 c | 120d | 99.06c | 8.25 a | 27.3bc | 79.32c | 28.99d | 2.4 c | 22.07d |
| Binadhan-17 | 58b | 130.5a | 97.5b | 8.97 a | 25.36c | 145.57a | 64.89a | 2.97 ab | 20.75e |

From the Table 24, it appears that IIBN-5 had the highest plant height ( 118 cm ) which was statistically similar with IIBN-18 and check varieties had shorter plant height. IRBN-5 had produced significantly higher number of effective tillers which was similar with check varieties whereas IRBN-11 had produced lowest number of effective tillers. The panicle length ranged 25.36 cm to 28.97 cm . IRBN-18 had produced longer panicle length ( 29.08 cm ) which was significantly similar with IRBN-5 while shortest panicle length ( 25.36 cm ) was found in Binadhan-17. The number of filled grains panicle ${ }^{-1}$ ranged from 79.32 to 147.78 . IRBN-18 had the highest number of filled grains panicle ${ }^{-1}(147.78)$ followed by Binadhan-17. The other check variety Binadhan-7 had the lowest number of filled grains per panicle (79.32). The line IRBN-5 took shortest time to mature which is significantly similar with check variety Binadhan-7. For yield, IRBN- 25 had produced higher yield $(3.41 \mathrm{~kg})$ than others and this lines also took shorter time (123 days) to mature.

Based on short duration and higher yield four lines (IRBN-11, IRBN-18, and IRBN-25) have been selected for next year evaluation.

## Advance Yield Trial of brown plant hopper resistant rice lines in Aman season

This experiment was carried out to assess insect resistant with high yield attributes of seven rice lines along with two check variety Binadhan-7 and Binadhan-17 tested in Aman at BINA Headquarter farm, Mymensingh and BINA Substation, Cumilla. Seeds were sown on $26^{\text {th }}$ July 2021 and transplanted to the field on 16 August 2021 at Mymensingh and Cumilla. The experiment followed RCB design with three replications. The size of a unit plot was $3.0 \mathrm{~m} \times 2.0$ m . Plant to plant distance was 20 cm and row to row distance was 20 cm . Recommended doses of nitrogen, phosphorus, potassium, sulphur and zinc were applied in the form of Urea, TSP, MoP , Gypsum and Zinc Sulphate. Cultural and intercultural practices were followed as and when necessitated. Data on plant height (cm), number of effective tiller plant ${ }^{-1}$, panicle length $(\mathrm{cm})$, number of filled grains panicle ${ }^{-1}$ were recorded after harvesting from 5 randomly selected competitive hills. Days to fifty $50 \%$ flowering and days to maturity was assessed plot basis. Recorded data were finally subjected to proper statistical analyses and are presented in Table 25.

Table 25. Mean performance of IBPHN rice lines along with check varieties during aman season 2021

From the Table 25, it is observed that the average range of plant height among the lines were ranged 103.11 cm to 128.49 cm . IRBPH-35 had the highest plant height ( 128.49 cm ) whereas IRBPH-5 had the lowest ( 103.11 cm ). The panicle length ranged 23.9 cm to 29.07 cm . The longest panicle length was observed in IRBPH-44, while shortest panicle length ( 23.99 cm ) was observed in IRBPH-5. The panicle length of check variety was 25.97 cm for Binadhan- 7 and 24.19 cm for Binadhan-17. There were 3 lines had longer panicle length than check varieties. The number of filled grains per panicle ranged from 189 to 253.00 . The highest number of filled grains (253.00) was observed in IRBPH-5, while lowest number of filled grains was observed in check varieties.
All lines produced higher yield than check varieties at both locations. Grain yield ranged from 4.80 to $6.82 \mathrm{t} \mathrm{ha}^{-1}$, IBPHN- 35 had maximum yield which was followed by IBPHN- 35, IBPHN38 and Binadhan- 7 had minimum yield (4.80tha ${ }^{-1}$ ).

Based on higher grain yield and short duration 5 lines (IRBPH-35, IRBPH-38, IRBPH-44 and IRBPH-21) have been selected and will be evaluated in the Advanced yield trial in next Aman season.

## Advanced yield trial of temperate nursery rice lines (IRTON) for Haor areas in Boro season

An experiment was carried out with two early and high yielding rice lines to assess the earliness and yield performance over two different locations of Bangladesh. BRRI dhan-28 was used as a check variety in Boro season. This experiment was carried out at four locations (BINA HQ farm, Mymensingh, BINA substation, Sunamganj BINA substation, Cumilla and on-farm, Bijoynagar, Brahmanbaria. Seeds were sown on 5th November 2021 and transplanted on $16^{\text {th }}$ December at Sunamganj and seeds were sown on 28th November 2021 and transplanted on 6,8 and 10th January 2022 at BINA HQ farm, Mymensingh, BINA substation, Cumilla and Onfarm respectively. The experiment followed by RCB design with three replications. The size of the unit plots were $3.0 \mathrm{~m} \times 4.0 \mathrm{~m}$. Seedlings were transplanted at 15 cm distance within rows of 20 cm apart. Recommended doses of nitrogen, phosphorus, potassium, sulphur and zinc were applied in the form of Urea, TSP, MOP, Gypsum and Zinc Sulphate. Cultural and intercultural practices were followed as and when necessitated. Data on various characters such as plant height, number of effective tillers plant ${ }^{-1}$, panicle length ( cm ), and filled grains panicle ${ }^{-1}$ were recorded after harvest from five randomly selected competitive plants. Days to Fifty \% flowering and days to maturity was assessed by plot basis. Grain yield data were recorded from an area of $1.0 \mathrm{~m}^{2}$ which was later converted to tha ${ }^{-1}$. Finally, all the recorded data were subjected to proper statistical analyses and are presented in Table 26.

From the Table 26, Results combined over four locations (three of on-station and one on-farm), there were significant difference in days to maturity among the lines and check variety. Days to maturity of BRRI dhan-28 were shortest (148 days) at all locations. IRTON-11 took statistically
same time ( 150.6 days) to mature like BRRI dhan-28. Plant height, in combined effect of varieties /lines IRTON-11 had shorter plant height ( 103.9 cm ) than others. Taller plant height ( 109.57 cm ) was found in IRTON-13 and it was similar at all locations. There were no significant differences of effective tillers per plant at Mymensingh, Cumilla and Sunamganj. At on farm (Bijoynagar) IRTON-11 produced significantly highest number of effective tillers (24.03). In combined effect of effective tillers per plant BRRI dhan-28 produced significantly lowest number of effective tillers (15.50), while IRTON-11 had produced highest number of effective tillers (19.38). In combined effect there was no significant difference in panicle length; BRRI dhan-28 had longer panicle length $(26.06 \mathrm{~cm})$. IRTON-13 had produced highest number of filled grains at all locations except Sunamganj. BRRI dhan-28 had produced highest number of filled grains at Sunamganj. In combined effect IRTON-13 had produced highest number (127.51) of filled grains.
Both lines had produced higher yield than check variety BRRI dhan-28 at all locations. IRTON13 produced the highest yield (6.4tha ${ }^{-1}$ ) followed by IRTON-11 ( 6.0 tha $^{-1}$ ). The grain size of the lines (IRTON-13 and IRTON-11) is slender. These two lines IRTON-13 and IRTON-11 have been selected for their higher yield and short duration and grain quality. These two lines (IRTON-13 and IRTON-11) have been selected for next year evaluation at haor areas of Bangladesh

## Advanced Yield Trial of Blast Nursery Rice Lines (IRBN) in Boro season

This experiment was conducted with six IRBN rice lines to select desirable lines having Blast resistance, higher grain yield, short duration, suitable for Boro season. The popular short duration Boro variety used as check variety at BINA Headquarter farm, Mymensingh. The seeds were sown on 25th December 2020 and transplanted to the field on 15 February 2021. The experiment was laid out in RCBD with three replications. Unit plot size was $3 \mathrm{~m} \times 2 \mathrm{~m}$ and spacing between hills and rows were 15 cm and 20 cm , respectively. Data on plant height, effective tillers hill $^{-1}$ (no.), filled grains panicle ${ }^{-1}$ and panicle length (cm) were recorded from five randomly selected plants from each plot. Maturity was assessed by plot basis. Grain yield data were recorded from an area of $6.0 \mathrm{~m}^{2}$. Finally, all the recorded data were subjected to proper statistical analyses and are presented in Table 27.

Table 27. Mean performance of IRBN rice lines along with check varieties during Boro season 2020-21

| Lines/ check varieties | Days to 50\% <br> Flowering | Days to maturity | Plant height (cm) | Effective tillers plant ${ }^{-1}$ (no.) | Panicle length (cm) | Filled Grains panicle ${ }^{-1}$ (no.) | Unfilled Grains panicle ${ }^{-1}$ (no.) | Grain yield $\operatorname{plot}^{-1}$ <br> (kg) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| IRBN-3 | 53.00a | 150.67b | 102.33ab | 9.11bc | 23.2Zab | 123.33cd | 27.78a | 4.45b |
| IRBN-9 | 45.33c | 145.67c | 102.89ab | 8.22cd | 25.44a | 134.56b | 16.00a | 4.20b |
| IRBN-14 | 45.00c | 152.00ab | 99.78 b | 7.22d | 23.44ab | 149.22a | 45.22a | 5.31a |
| IRBN-18 | 48.67b | 142.33d | 101.11ab | 7.22d | 23.44ab | 138.56b | 16.67a | 4.47b |
| IRBN-32 | 49.00b | 152.67a | 105.22a | 10.00ab | 24.00ab | 115.89e | 19.45a | 4.51b |
| IRBN-34 | 48.00 b | 145.67c | 89.11c | 10.45a | 22.67 ab | 127.56c | 33.22a | 5.39a |
| BRRIdhan-28 | 41.33d | 142.67 d | 88.89c | 7.52d | 21.56b | 119.78 e | 17.67a | 3.94c |
| CV | 1.12 | 0.45 | 1.90 | 4.67 | 4.17 | 1.47 | 47.63 | 2.68 |
| SE | 0.43 | 0.54 | 1.53 | 0.33 | 0.80 | 1.56 | 9.78 | 11.33 |

From the Table 27, it is observed that all IRBN lines had produced taller plant than check variety. IRBN-18 had the highest plant height ( 105.22 cm ) whereas the check variety BRRIdhan28 had the lowest. The highest number of effective tillers plant ${ }^{-1}$ (14.45) was observed in IRBN34 which was significantly similar with IRBN-32 (10.00. The lowest number of effective tillers plant $^{-1}$ (7.22) was found in IRBN-14 and IRBN-18. The panicle length ranged 21.56 cm to 25.44 cm . The longest panicle length ( 25.44 cm ) was observed in IRBN-9 which was significantly similar with other IRBN lines, while shortest panicle length ( 21.56 cm ) observed in check variety BRRIdhan-28. The number of filled grains panicle ${ }^{-1}$ ranged from 115.89 to 149.00 . IRBN-14 had produced significantly higher number of filled grains while IRBN-32 had the lowest. The check variety took the lowest time to mature than the all IRBN lines and IRBN-32 took the highest time to mature. There are all IRBN lines had produced higher grain yield than check variety BRRI dhan-28. Grain yield (kg) ranged from 3.94 kg to 5.39 kg . IRBN-32 and IRBN-14 had maximum statistically same yield while check variety BRRIdhan-28 had minimum yield per plot $(3.94 \mathrm{~kg})$.

Based on higher seed yield 5 IRBN rice lines (IRBN-14, IRBN-18, IRBN-32 and IRBN-34) have been selected and will be evaluated in next Boro season.

## Preliminary yield trial of advanced rice lines

This trial was carried out with four rice lines derived from Binadhan-16×NERICA-4 along with BRRI dhan 49 as check variety to assess the yield performance over locations. The experiment was conducted at BINA HQs farm Mymensingh, BINA sub-stations farm Sunamganj and Magura during the T. Aman season of 2021. The trial followed the RCB design with three replications having the unit plot size of $4 \mathrm{~m} \times 3 \mathrm{~m}$. The row-to-row and plant-to-plant distances were 20 cm and 15 cm , respectively. Standard production practices for water and nutrition management, and disease and pest control were followed.

Data on the agronomic performances across the three locations were summarized in Table 28. Plant height varied from 97.5 cm (B-32-3-4) to 125.1 cm (B-32-2-3) indicating all the lines were intermediate in case of plant height. The height of the check variety (BRRI dhan49) was 110.9 cm . The line R-30-1-1 took the shortest period (108 days) to mature while the check variety matured at 130 days. Yield was varied from $5.4 \mathrm{t} / \mathrm{ha}$ (R-30-1-1 and B-33-1-2) to $6.4 \mathrm{t} / \mathrm{ha}$ (B-32-$2-3$ ). The check variety produced 5.8 t /ha yield indicating that line B-32-2-3 produced $10.34 \%$ more yield than the check.

Estimation of the heritability\% depicted that the plant height (0.92) and growth duration (0.96) were highly heritable traits in the studied lines while heritability in case of yield (0.35) was lower.

Table 28: Agronomic performances of the tested lines/variety in Preliminary Yield Trial during T. Aman 2021

| Designation | Plant height (cm)* | Growth duration (days) | Yield (t/ha) * |
| :--- | :---: | :---: | :---: |
| R-30-1-1 | 123.8 | 108 | 5.4 |
| B-32-2-3 | 125.1 | 119 | 6.4 |
| B-32-3-4 | 97.5 | 109 | 6.0 |
| B-33-1-2 | 116.0 | 109 | 5.4 |
| BRRI dhan49 | 110.9 | 130 | 5.8 |
| LSD (0.5) | 5.2 | 2.6 | 0.7 |
| Heritability (\%) | 0.92 | 0.96 | 0.35 |
| *Mean of three locations (Mymensingh, Sunamganj and Magura) |  |  |  |

*Mean of three locations (Mymensingh, Sunamganj and Magura)
Data on the grain quality parameters across the three locations were summarized the Table 29. The highest head rice recovery $\%$ was found in the line R-30-1-1 which was almost similar to the check variety (69.61). The lines B-32-2-3 and B-33-3-4 had the head rice recovery\% 68.00 and 64.37, respectively. The line B-32-2-3 had the longest grain ( 6.70 mm ) and the highest $\mathrm{L} / \mathrm{B}$ ratio (3.10) indicating that the line produced long slender grain. Other lines produced long medium grain and the check variety produced medium grain.

Table 29: Grain quality parameters of the tested lines/variety in Preliminary Yield Trial during T.
Aman 2021

| Designation | Head rice <br> recovery $(\mathbf{\%})$ | Grain length <br> $(\mathbf{m m})$ | Grain breadth <br> $(\mathbf{m m})$ | L/B ratio |  <br> shape |
| :--- | :---: | :---: | :---: | :---: | :---: |
| R-30-1-1 | 70.01 | 6.03 | 2.04 | 2.94 | LM |
| B-32-2-3 | 68.00 | 6.70 | 2.16 | 3.10 | LS |
| B-32-3-4 | 64.37 | 6.48 | 2.45 | 2.66 | LM |
| B-33-1-2 | 57.83 | 6.32 | 2.43 | 2.62 | LM |
| BRRI dhan49 | 69.61 | 5.83 | 1.93 | 2.99 | MM |

Considering all the aspects it is quite evident that the line B-32-2-3 and B-32-3-4 were selected for further evaluation.

## Preliminary Yield Trial of Brown plant hopper resistant rice lines in Boro season

This experiment was conducted to evaluate rice lines for insect resistance with high yield attributes. Four rice lines along with one check variety BRRI dhan-28 tested in Boro season at BINA Headquarter farm, Mymensingh. Seeds were sown on 22nd December 2020 and transplanted to the field on 10th February 2021. The experiment followed RCB design with three replications. The size of a unit plot was $3.0 \mathrm{~m} \times 4.0 \mathrm{~m}$. Plant to plant distance was 15 cm and row to row distance was 20 cm . Recommended doses of nitrogen, phosphorus, potassium, sulphur and zinc were applied in the form of Urea, TSP, MoP, Gypsum and Zinc Sulphate. Cultural and intercultural practices were followed as and when necessitated. Data on plant height (cm), number of effective tiller plant ${ }^{-1}$, panicle length ( cm ) and filled grains panicle ${ }^{-1}$ were recorded after harvesting from 5 randomly selected competitive hills. Days to $50 \%$ flowering and maturity were assessed plot basis. Recorded data were finally subjected to proper statistical analyses and are presented in Table 30.
Table 30. Mean performance of IBPHN rice lines along with check varieties at BINA Hqs, Mymensingh during boro season 2020-21

| Lines/ check varieties | Days to fifty \% flowering | Days to maturity | Plant <br> height <br> (cm) | Effective tillers plant ${ }^{-1}$ (no.) | Panicle <br> length <br> (cm) | Filled <br> Grains Panicle ${ }^{-1}$ <br> (no.) | Unfilled Grains Panicle ${ }^{-1}$ (no.) | Grain <br> yield <br> plot $^{-1}$ <br> (kg) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| IRBPHN-2 | 67.33c | 144.00b | 93.56 b | 10.11a | 25.00a | 118.33a | 23.67a | 7.39a |
| IRBPHN-5 | 72.67b | 151.67a | 92.33b | 10.00a | 21.22b | 155.56a | 23.56a | 6.79b |
| IRBPHN-18 | 76.33a | 153.33a | 103.33a | 8.89a | 24.56a | 112.78a | 21.78a | 6.11c |
| IRBPHN-38 | 76.33a | 151.33a | 97.78b | 9.78a | 24.78a | 125.67a | 36.78a | 5.68c |
| BRRI dhan-28 | 67.00c | 142.00b | 94.67b | 8.55a | 21.78b | 114.78a | 19.44a | 6.09c |
| CV | 1.22 | 0.58 | 1.27 | 2.57 | 2.94 | 2.63 | 14.76 | 1.46 |
| SE | 0.72 | 0.70 | 1.00 | 0.20 | 0.56 | 2.69 | 3.02 | 7.66 |

From the Table 30, it was observed that the average range of plant height among the lines and check variety were 92.33 cm to 103.33 cm . The line IRBPH-18 had the highest plant height whereas IRBPH-5 had the lowest and statistically similar with other lines. For effective tillers plant ${ }^{-1}$, there was no significantly difference among the rice lines and check varieties. The panicle length ranged 21.22 cm to 25.00 cm . All lines had longer panicle length than check varieties except IRBPH-5. The longest panicle length ( 25.00 cm ) was observed in IRBPH-2 statistically similar with IRBPH-18 and IRBPH-38 while the shortest panicle length (21.22) in IRBPH-5.There were no significant differences in filled and unfilled grains per panicle. There were no lines earlier than check varieties.

Grain yield plot ${ }^{-1}$ ranged from 6.68 kg to 7.39 kg . IBPHN-2 had maximum yield $(7.39 \mathrm{~kg}$ ) whereas IBPHN-38 had minimum yield $(5.68 \mathrm{~kg})$. There are four lines (IRBPH-2, IRBPH-5,

IRBPH-18 and IRBPH-44) produced higher grain yield (kg/plot) than check variety BRRI dhan28.

Based on higher grain yield 2 lines (IRBPH-2, IRBPH-5) have been selected for Advanced yield trial in next Boro season.

## Preliminary Yield Trial of upland (IURON) rice lines

Fifteen IURON rice lines were evaluated through this observation trial to assess the performance of improved yield component for Boro season. This experiment was conducted at the BARD experimental field, Kotbari, Cumilla during Boro season 2021-22. Seeds were sown on $25^{\text {th }}$ December 2020 and transplanted to the field on 1st February 2021. The experiment was laid out in RCBD with two replications. Unit plot size was $2 \mathrm{~m} \times 2 \mathrm{~m}$ and spacing between hills and rows were 15 cm and 20 cm , respectively. Data on plant height ( cm ), effective tillers hill- ${ }^{1}$ (no.), number of filled grain plant ${ }^{-1}$ and panicle length ( cm ) were recorded from five randomly selected plants from each plot. Days to $50 \%$ flowering and days to maturity were assessed by plot basis. Grain yield data were recorded from an area of $6.0 \mathrm{~m}^{2}$. Finally, all the recorded data were subjected to proper statistical analyses and are presented in Table 31.

Table 31. Mean performance of IURON rice lines during Boro season 2020-21

| CV(\%) | 0.93 | 5.15 | 5.08 | 19.67 | 16.85 | 7.77 | 21.71 | 9.31 | 8.07 |
| Hsd | 2.06 | 16.94 | 3.81 | 8.75 | 7.08 | 22.369 | 29.783 | 6.598 | 0.1712 |

It appeared that IURON-17/38 had the highest plant height ( 120.00 cm ) whereas IURON-05(1) had the lowest $(98.7 \mathrm{~cm})$. Days to maturity ranged from 126 days to 140 days. IURON-38/1 took the shorter period (126 days) to mature which was significantly similar with IURON-05/1. IURON- 17/30 had longest panicle length ( 27.7 cm ) whereas Binadhan- 24 had shortest panicle length $(21.0 \mathrm{~cm})$. Total tiller /plant and effective tiller/plant had not significantly differed among the lines and check varieties. The highest number of effective tillers/hill (16) was found in IURON -05/1, and IURON- 17/15. The number of filled grains per panicle ranged from 57.00 to 122.00. IURON- 17/16 and IURON - $15 / 2$ had the highest number of filled grains per panicle and IURON- 17/36 had the lowest number of filled grains per panicle. Grain yield (kg) ranged from 0.505 kg to 0.814 kg . IURON- $17 / 36$ had maximum yield while IURON- $05 / 2 \mathrm{had}$ minimum yield. Only line IURON- 17/36 had produced higher yield than check varieties.
Based on early maturity and higher seed yield 5 IURON rice lines (IURON- 38/1), IURON -05/1, IURON- 17/36, IURON- 17/16 and IURON- 17/30 have been selected and will be evaluated in next Boro season and Aus season in Cumilla.

## Observation yield trial of high yielding Boro rice mutants

This trial was carried out with 18 rice mutants derived from NERICA-4 and Binadhan-17. The experiment was conducted at BINA HQs farm Mymensingh. The unit plot size was $2 \mathrm{~m} \times 2 \mathrm{~m}$. The row-to-row and plant-to-plant distances were 20 cm and 15 cm , respectively. Standard production practices for water and nutrition management, and disease and pest control were followed.

Six mutants were selected from the trial based on their agronomic performance. The mutants matured in between 146 and 147 days. All the mutants, except for the mutant B17-19-1, had intermediate plant height. The plant height ranged from 94cm (N4/M6/P-5 (1)-1) to 122 cm (B17-19-1). Four mutants produced yield greater than $8 \mathrm{t} / \mathrm{ha}$ namely N4/M6/P-3-4-1 (9.69 t/ha), N4/M6/p-5(1)-1 (9.04 t/ha), N4/M6/P-9(1)-1 (8.58 t/ha), N4/M6/P-12(2)-1 (8.26 t/ha). The other two mutants, N4/M6/P-1(1)-1 and B17-19-1 produced $7.72 \mathrm{t} / \mathrm{ha}$ and 7.59 t /ha yield, respectively. The parent NERICA-4 and Binadhan-17 produced $4.01 \mathrm{t} / \mathrm{ha}$ and $6.80 \mathrm{t} / \mathrm{ha}$ yield, respectively.

Table 32: Agronomic performance of the selected mutants in the Boro 2021-2022 season

| Mutants | Days to <br> flowering | Days to <br> maturity | Plant height (cm) | Yield (t/ha) |
| :---: | :---: | :---: | :---: | :---: |
| N4/M6/p-5(1)-1 | 111 | 146 | 94 | 9.04 |
| N4/M6/P-9(1)-1 | 113 | 146 | 100 | 8.58 |
| N4/M6/P-3-4-1 | 110 | 146 | 102 | 9.69 |
| N4/M6/P-12(2)-1 | 117 | 146 | 111 | 8.26 |
| N4/M6/P-1(1)-1 | 113 | 147 | 95 | 7.72 |
| B17-19-1 | 118 | 147 | 122 | 7.59 |
| NERICA-4 | 110 | 142 | 105 | 4.01 |
| Binadhan-17 | 113 | 145 | 100 | 6.80 |

## Observation trial of Bacterial blight nursery rice lines (IRBBN) in Aman season

This experiment was carried out to assess disease tolerant, short duration with high yield attributes of five rice lines along with two check variety Binadhan-7 and Binadhan-17 tested in Aman' 2021 at BINA Headquarter farm, Mymensingh and BINA substation, Cumilla. Seeds were sown on 4th July 2021 and transplanted to the field on 8th August 2021. The experiment followed RCB design with three replications. The size of a unit plot was $3.0 \mathrm{~m} \times 2.0 \mathrm{~m}$. Plant to plant distance was 20 cm and row to row distance was 20 cm . Recommended doses of nitrogen, phosphorus, potassium, sulphur and zinc were applied in the form of Urea, TSP, MoP, Gypsum and Zinc Sulphate. Cultural and intercultural practices were followed as and when necessitated. Data on plant height (cm), number of effective tiller plant ${ }^{-1}$, panicle length (cm) and number of filled grains panicle ${ }^{-1}$ were recorded after harvesting from 5 randomly selected competitive hills. Days to $50 \%$ flowering and days to maturity were assessed plot basis. Recorded data were finally subjected to proper statistical analyses and are presented in Table 33.

| SE | 0.76 | 0.70 | 1.58 | 0.62 | 0.76 | 0.69 | 4.14 | 3.37 | 0.63 | 0.28 |

From the Table 33, Days to maturity of IRBBN-31 and check variety Binadhan-17 took longest time (110 days) and IRBBN-9, IRBBN-17 took shortest time (106 days) to mature at both locations. All the lines produced taller plant than check varieties. The mean data of plant height in combined over locations, shortest plant height ( 101.42 cm ) was found in check variety Binadhan-17 and it was statistically similar with Binadhan-7 (103.42 cm). Total tillers were found highest in check variety Binadhan-7 (13.00) at Cumilla but it was statistically similar among the lines and check varieties at Mymensingh. Binadhan-7 produced highest number of effective tillers (13.00) at Cumilla and it was similar with other check variety and line IRBBN-9. All lines had produced taller panicle length than check varieties and IRBBN-9 ( 28.71 cm ) had produced tallest panicle length at both locations. IRBBN-17, IRBBN-18, IRBBN-31 and check variety Binadhan-17 had produced highest numbers of filled grains panicle ${ }^{-1}$ (125). The check variety Binadhan-17 had produced highest yield ( 5.85 tha $^{-1}$ ) than other lines and check variety. This experiment with these lines will be repeated for further evaluation in next year.

## Observation trial of Bacterial blight nursery rice lines (IRBBN) in Boro season

This experiment was carried out to assess disease tolerant, short duration with high yield attributes of seven rice lines along with one check variety BRRIdhan-28 tested in Boro' 2020-21 season at BINA Headquarter farm, Mymensingh. Seeds were sown on $15^{\text {th }}$ December 2020 and transplanted to the field on $31^{\text {st }}$ January 2021. The experiment followed RCB design with three replications. The size of a unit plot was $3.0 \mathrm{~m} \times 2.0 \mathrm{~m}$. Plant to plant distance was 15 cm and row to row distance was 20 cm . Recommended doses of nitrogen, phosphorus, potassium, sulphur and zinc were applied in the form of Urea, TSP, MoP, Gypsum and Zinc Sulphate. Cultural and intercultural practices were followed as and when necessitated. Data on plant height (cm), number of effective tiller plant ${ }^{-1}$, panicle length (cm) and number of filled grains panicle ${ }^{-1}$ were recorded after harvesting from 5 randomly selected competitive hills. Days to $50 \%$ flowering and days to maturity were assessed plot basis. Recorded data were finally subjected to proper statistical analyses and are presented in Table 34.

Table 34. Mean performance of IRBBN rice lines along with check variety at BINA Hqs, Mymensingh during Boro season 2021-22

| IRBBN-22 | 71.00c | 144.00a | 109.56a | 10.11a | 25.67a | 134.56b | 34.56a | 4.31b |
| IRBBN-26 | 65.67d | 144.00a | 96.33c | 7.44c | 26.11a | 123.00bc | 35.78a | 4.13b |
| IRBBN-31 | 75.00a | 143.00a | 105.33abc | 8.78b | 26.56a | 128.89bc | 33.33a | 3.64d |
| IRBBN-32 | 70.33cd | 137.33a | 99.89bc | 10.78a | 24.22a | 188.33a | 23.44a | 4.80a |
| BRRIdhan-28 | 66.00d | 134.00a | 97.22c | 10.44a | 23.44a | 109.45c | 28.56a | 3.77c |
| CV | 0.59 | 0.29 | 3.12 cv | 8.56 | 4.42 | 5.73 | 28.81 | 2.36 |
| SE | 0.33 | 0.33 | 2.64se | 0.66 | 0.89 | 6.40 | 6.29 | 12.54 |

From the Table 34, it appeared that Days to maturity among the IRBBN lines and check variety ranged from 134.33 days to 144.00 days. There were no earlier lines than check variety BRRIdhan-28. IRBBN-26 had shorter plant height than others and IRBBN-22 had taller plant height ( 107.89 cm ) which is significantly similar with IRBBN-9 and IRBBN-31. There was no significant difference in panicle length.

All the IRBBN lines had produced higher grain yield than check variety BRRI dhan-28 except IRBBN-31. Grain yield ( kg ) ranged from 3.64 kg to 4.98 kg . IRBBN-9 had maximum yield which was significantly similar with IRBBN-6, IRBBN-32 while IRBBN-31 and BRRIdhan-28 had minimum yield ( 3.64 and 3.77 kg ).

Based on higher grain yield and early maturity 7 lines (IRBBN-6, IRBBN-9, IRBBN-31 and IRBBN-32) have been selected and will be evaluated in the Advanced yield trial in next Boro season.

## Handling of segregating population

Screening of advanced breeding lines of rice (oryza sativa l.) for salinity tolerance at the seedling stage through morphological and molecular marker(s)

This experiment was set up to evaluate injury of salt stress on different rice genotypes at seedling stage in hydroponic system followed IRRI standard protocol (1997). After two or three days of salinization, salt stress symptoms were visualized. Injury scoring of rice genotypes was
performed by Standard Evaluation Score (SES) (IRRI, 1997) chart at seedling stage under 8, 10 and $12 \mathrm{dS} / \mathrm{m}$ salinity levels. The range of scoring was 1 to 9 . Final scoring was done at 21 and 23 days after salinization of rice seedlings. Table 35 shows the tolerance level of different rice genotypes under different saline conditions. In salinized setup, different genotypes showed wide variation. None of the genotypes showed high salt tolerance at EC-8, 10 or $12 \mathrm{dS} / \mathrm{m}$. Among the 25 genotypes, 18 genotypes (IRSSTN 1, IRSSTN 2, IRSSTN 3, IRSSTN 4, IRSSTN 6, IRSSTN 7, IRSSTN 10, IRSSTN 11, IRSSTN 12, IRSSTN 13, IRSSTN 14, IRSSTN 16, IRSSTN 19, IRSSTN 20, IRSSTN 23, IRSSTN 24, FL-478 And Binadhan-10) showed tolerance at $8 \mathrm{dS} / \mathrm{m}$, SEVEN genotypes (IRSSTN 9, IRSSTN 15, IRSSTN 17, IRSSTN 18, IRSSTN 21, IRSSTN 22, Binadhan-7) showed moderate tolerance. Eleven genotypes (IRSSTN 1, IRSSTN 2, IRSSTN 4, IRSSTN 6, IRSSTN 12, IRSSTN 13, IRSSTN 16, IRSSTN 20, IRSSTN 23, FL-478 and Binadhan-10) were identified as tolerant at $10 \mathrm{dS} / \mathrm{m}$ whereas twelve of the genotypes (IRSSTN 3, IRSSTN 10, IRSSTN 11, IRSSTN 13, IRSSTN 14, IRSSTN 15, IRSSTN 17 IRSSTN 18, IRSSTN 19, IRSSTN21, IRSSTN 22 and IRSSTN 24) were moderately tolerant, 2 genotypes (IRSSTN 9 and Binadhan-7) were susceptible. At EC-12 dS/m, nine genotypes (IRSSTN 2, IRSSTN 6, IRSSTN 12, IRSSTN 13, IRSSTN 16, IRSSTN 20, IRSSTN 23, FL-478 and Binadhan-10) showed tolerance. Six genotypes (IRSSTN 1, IRSSTN 10, IRSSTN 14, IRSSTN 15, IRSSTN 17 and IRSSTN 18) were found as moderately tolerant, nine genotypes (IRSSTN 3, IRSSTN 4, IRSSTN 7, IRSSTN 11, IRSSTN 19, IRSSTN 21, IRSSTN 22, IRSSTN 24 and Binadhan-7) were identified as susceptible and IRSSTN 9 found highly susceptible to salt stress at12dS/m.

Table 35: SES score of 25 rice genotypes under salinized condition grown in hydroponic system at the seedling stage

| Genotypes | EC- 8dS/m |  | EC-10dS/m |  | EC-12dS/m |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| FL-478 | 3 | T | 3 | T | 3 | T |
| 9 Scale, wh | highly | $3=$ tole | $=$ moderat | (MT), 7 | (S) and | usceptible |

Twenty-five rice genotypes were analyzed exploiting 12 loci for SSR marker-based DNA fingerprinting technique for salinity tolerance. The bands obtained, were compared to the band of salt tolerant variety FL478, Binadhan-10 and susceptible one Binadhan-7 as these three genotypes were used as check. The detailed information which were found after analyzing the fingerprinting data are briefly discussed and presented below.

Both the phenotypic and molecular screening found some lines of rice those showed tolerance for salinity these are: IRSSTN 12, IRSSTN 13 and IRSSTN 16. These lines can be used for further improvement for developing salinity and tolerant rice varieties.

## Growing $\mathbf{F}_{\mathbf{2}} \boldsymbol{\&} \mathbf{F}_{\mathbf{3}}$ population rice through Field RGA

This experiment was set up for rapid advancement of segregating population for shortening breeding cycle and development of large RIL population. A total of $20 \mathrm{~F}_{2}$ and $25 \quad \mathrm{~F}_{3}$ populations were grown in T. Aman 2021 season. Single seed progenies from single panicle of one plant were grown in the RGA nursery in field. In the field, part of the panicle was sown directly on the soil. No thinning or pruning was done. Around 30 days old seedlings were transplanted in a $5.4 \mathrm{~m} \times 2$ rows plot with a spacing of $25 \mathrm{~cm} \times 15 \mathrm{~cm}$. Single seedlings was used for transplanting. Fertilizers were applied @ 200 kg urea, 62 kg TSP, $50 \mathrm{~kg} \mathrm{MoP}$,56 kg gypsum and 5 kg zinc sulphate/ha. Urea was applied in equal three splits at 10,25 and 40 days after transplanting. The fertilizers other than urea were applied as basal during final land preparation. Water stress was imposed at 30 days after transplanting and it was continued until PI stage. Appropriate pest management practices were done as and when necessary.
During harvesting at maturity, one panicle was collected from each plant of all the crosses in different times and the plant was uprooted. Harvested seeds remaining in the panicles were dried and subjected for dormancy breakage to initiate next cycle of RGA immediately. For dormancy breaking, at first, sun-drying was done for three days followed by oven drying with $50^{\circ} \mathrm{C}$ temperature for 72 hours. Panicles of 305 individuals from $20 \mathrm{~F}_{2}$ and $25 \mathrm{~F}_{3}$ populations were harvested at the time of maturity and preserved and processed with proper labels.

## Growing of $\mathbf{F}_{2}$ generation of Binadhan-17, BRRI dhan29 \& Binadhan-24 with Binadhan-5 cross

Accordingly, a minimum of an average rough rice yield target of 9.11 t ha- 1 has been set for 2050. However, this target cannot be achieved equally across all the geographic regions of Bangladesh. Because, the country has various 'rice types' based on specific ecosystems, and also due to the pressing 'needs'. All these 'rice types' have different situation-specific yield potentials and area coverage. The breeding objective was to develop a high yielding rice variety will be grown in boro season that will achieve the future target genetic yield potential (GYP) in Bangladesh
$70 \mathrm{~F}_{2}$ populations were developed from crossing between Binadhan-5 with Binadhan-17 and Binadhan-24 to select high yielding, short duration, and lodging resistant plant/progenies. This experiment was conducted at Boro season, 2021 for selecting desirable characters at BINA Head quarters farm, Mymensingh. The $\mathrm{F}_{2}$ population was put at Rapid Generation Advance (RGA) trail to develop $\mathrm{F}_{3}$ population

Considering the yield \& yield attributes, the promising lines will be evaluated for the next generation

## Screening of $\mathbf{F}_{5}$ population of Binadhan- $7 \times$ Biroi crosses

Biroi is a traditional local rice variety of Bangladesh containing red pericarp in grain and considered as red rice. Higher plant height, longer duration and lodging susceptibility are the key
characteristics of Biroi cultivar. Stem lodging hindrances the photosynthetic effectiveness of the canopy that affects the grain filling. Hence the rice grain yield and quality reduced by $60-80 \%$ as photosynthesis is directly associated with lodging. Modern breeding techniques including mutation could improve the lodging and yield of red rice to overcome this problem. Successful breeding for crop improvement, however, depends on genetic variation in the parents which limit breeding progress and/or yield and quality crop improvements. The objective of this research is to develop a lodging tolerant premium quality red pericarp rice variety that will maintain the nutritional balance as well as the food demand in the world prospective.

Seeds of $\mathrm{F}_{5}$ population of Binadhan- $7 \times$ Biroi were sown on 13 July, 2021 and transplanted on 12 August, 2021 at BINA Headquarter, Mymensingh by maintaining plant to plant and row to row distance 15 cm and 20 cm respectively. The experiment was followed by non-replicated design. The size of the unit plots were $1 \mathrm{~m} \times 2 \mathrm{~m}$. Recommended doses of nitrogen, phosphorus, potassium, sulphur and zinc were applied in the form of Urea, TSP, MoP, Gypsum and Zinc Sulphate. Cultural and intercultural practices were followed as and when necessitated. Data on plant height, number of effective tillers plant ${ }^{-1}$, panicle length, and filled and unfilled grains panicle ${ }^{-1}$ were recorded after harvest from 5 randomly selected competitive plants. Maturity was assessed plot basis. Finally, all the recorded data were subjected to proper statistical analyses as per design and are presented in Table 36.

Table 36. Grain yield and yield components of $F_{5}$ population of Binadhan- $7 \times$ Biroi cross that were sown at BINA Headquarter, Mymensingh

| Variety/Mutant | Duration | Plant <br> height(cm) | Effective <br> Tiller | Panicle <br> length $(\mathrm{cm})$ | Filled <br> grain | 1000 seed <br> wt.(g) |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| B-P-2-38-1-1 | $134 \pm 1.47$ | $94 \pm 2.97$ | $11 \pm 0.73$ | $26 \pm 0.44$ | $100 \pm 4.95$ | $21 \pm 0.34$ |
| B-P-2-38-1-2 | $130 \pm 1.47$ | $94 \pm 2.97$ | $15 \pm 0.73$ | $24 \pm 0.44$ | $129 \pm 4.95$ | $20.8 \pm 0.34$ |
| B-P-2-38-1-3 | $124 \pm 1.47$ | $104 \pm 2.97$ | $13 \pm 0.73$ | $27 \pm 0.44$ | $100 \pm 4.95$ | $21.6 \pm 0.34$ |
| B-P-2-38-1-4 | $129 \pm 1.47$ | $96 \pm 2.97$ | $11 \pm 0.73$ | $25 \pm 0.44$ | $96 \pm 4.95$ | $21.44 \pm 0.34$ |
| B-P-2-38-1-5 | $127 \pm 1.47$ | $92 \pm 2.97$ | $9 \pm 0.73$ | $25 \pm 0.44$ | $90 \pm 4.95$ | $22.1 \pm 0.34$ |
| B-P-2-38-1-6 | $130 \pm 1.47$ | $97 \pm 2.97$ | $11 \pm 0.73$ | $26 \pm 0.44$ | $98 \pm 4.95$ | $20 \pm 0.34$ |
| B-P-2-38-1-7 | $121 \pm 1.47$ | $91 \pm 2.97$ | $11 \pm 0.73$ | $25 \pm 0.44$ | $92 \pm 4.95$ | $20.21 \pm 0.34$ |
| B-P-2-38-1-8 | $125 \pm 1.47$ | $94 \pm 2.97$ | $8 \pm 0.73$ | $24 \pm 0.44$ | $112 \pm 4.95$ | $23 \pm 0.34$ |
| B-P-2-38-1-9 | $121 \pm 1.47$ | $102 \pm 2.97$ | $15 \pm 0.73$ | $27 \pm 0.44$ | $146 \pm 4.95$ | $21.1 \pm 0.34$ |
| B-P-2-38-1-10 | $129 \pm 1.47$ | $102 \pm 2.97$ | $19 \pm 0.73$ | $29 \pm 0.44$ | $140 \pm 4.95$ | $22 \pm 0.34$ |
| B-P-2-38-1-11 | $130 \pm 1.47$ | $103 \pm 2.97$ | $11 \pm 0.73$ | $24 \pm 0.44$ | $101 \pm 4.95$ | $20.42 \pm 0.34$ |
| B-P-2-38-1-12 | $127 \pm 1.47$ | $100 \pm 2.97$ | $12 \pm 0.73$ | $25 \pm 0.44$ | $105 \pm 4.95$ | $20.31 \pm 0.34$ |
| B-P-2-38-1-13 | $135 \pm 1.47$ | $94 \pm 2.97$ | $8 \pm 0.73$ | $23 \pm 0.44$ | $95 \pm 4.95$ | $20.1 \pm 0.34$ |
| B-P-2-38-1-14 | $131 \pm 1.47$ | $103 \pm 2.97$ | $9 \pm 0.73$ | $27 \pm 0.44$ | $100 \pm 4.95$ | $20.6 \pm 0.34$ |
| B-P-2-38-1-15 | $125 \pm 1.47$ | $93 \pm 2.97$ | $13 \pm 0.73$ | $26 \pm 0.44$ | $138 \pm 4.95$ | $21.6 \pm 0.34$ |
| Biroi (P) | $140 \pm 1.47$ | $143 \pm 2.97$ | $8 \pm 0.73$ | $22 \pm 0.44$ | $76 \pm 4.95$ | $23.6 \pm 0.34$ |
| Binadhan-7(P) | $115 \pm 1.47$ | $98 \pm 2.97$ | $12 \pm 0.73$ | $23 \pm 0.44$ | $121 \pm 4.95$ | $24.9 \pm 0.34$ |

Significant variation was observed in term of duration among the crossing population. All the progenies had shorter plant height comparing to the parent Biroi. The population B-P-2-38-1-7 had shorter plant height $(91 \mathrm{~cm})$ comparing to the parent Biroi. The population B-P-2-38-1-10 had higher (19) effective tillers comparing to the check variety Binadhan-7 (12). In B-P-2-38-1-10 population had longest Panicle length ( 29 cm ). The progeny B-P-2-38-1-15 had highest number (138) of filled grains panicle ${ }^{-1}$ contrasting to other crossing population and the check variety Binadhan-7 (121). All the crossing population had lower 1000 grain weight comparing to the Biroi and Binadhan-7 parents (Table 36).

Considering the yield \& yield attributes, the promising lines will be evaluated for the next generation.

## Growing $\mathbf{M}_{3} \mathbf{R}_{1}$ population of sticky rice

To create genetic variability mainly for stickiness, seeds of three rice varieties (Huachinbio, Fukunishiki and Nipponbare) were irradiated with Cobalt ${ }_{60}$ gamma rays at 200, 250, $300 \& 350 \mathrm{~Gy}$ doses. Experiment was carried out during Boro season 2021-22. The experiment was followed non-replicated design with spacing 15 cm and 20 cm . Recommended doses of nitrogen, phosphorus, potassium, sulphur and zinc were applied in the form of Urea, TSP, MoP, Gypsum and Zinc Sulphate. Cultural and intercultural practices were followed as when necessitated. Seeds were harvested separately for next generation.

## Growing M2 and M3 of Chinigura and Kataribhog

The $\mathrm{M}_{2}$ population of Chinigura and Kataribhog ( $250 \mathrm{~Gy}, 300 \mathrm{~Gy}$, and 400 Gy ) were grown in Aman 2021-2022 season. In the $\mathrm{M}_{2}$ population 43 plants from Chinigura and 35 plants from Kataribhog were selected based on plant height and earliness. The selected Kataribhog plants matured as early as 106 days and as late as 144 days while the parent took 155 days to mature (Table 37). The plant height ranged from 64 cm to 196 cm while parent's plant height was 138 cm . The selected Chinigura plants matured in between 106 to 144 days while the parent matured at 148 days. The plant height ranged between 83 cm to 195 cm while the parent's height was 154 cm (Table 38).
Table 37: Descriptive statistics of the selected $\mathrm{M}_{2}$ population of Kataribhog

| Feature | Days to maturity | Plant height (cm) | Total tiller | Effective tiller |
| :---: | :---: | :---: | :---: | :---: |

## Generation advancement through field RGA

To develop high-yielding and fine-quality rice with aroma or without aroma total of 4 crosses were made and true hybrid was confirmed with SSR markers.

## Ping $\mathbf{3} \times$ Binadhan -11

To increase the heterosis for the yield and yield contributing traits, Ping 3 and Binadha-11 were crossed. The $\mathrm{F}_{2}$ generation was cultivated under field settings utilizing the Field Rapid Generation Advancement (RGA) method after the $\mathrm{F}_{1}$ seeds were harvested. In Aman 2021-2022, $540 \mathrm{~F}_{2}$ genotypes were raised. At maturity, a single panicle from each genotype was collected. A similar approach was used in the next Boro season (2021-2022) to manage the $\mathrm{F}_{3}$ population. Sixty genotypes in Aus 2021-2022 failed to germinate, making the $\mathrm{F}_{4}$ population size 480.

## Binadhan- $12 \times$ Binadhan-17

Binadhan-12 and Binadhan 17 were crossed to increase grain yield and quality. After the $\mathrm{F}_{1}$ seeds were harvested, the $\mathrm{F}_{2}$ generation was grown using the Field Rapid Generation Advancement (RGA) technique in field conditions. There were $300 \mathrm{~F}_{2}$ genotypes produced in Aman 20212022. Each genotype's mature panicle was harvested as a single unit. The $\mathrm{F}_{3}$ population was managed using a similar strategy over the next Boro season (2021-2022). The $\mathrm{F}_{4}$ population in Aus 2021-2022 has 260 members since 40 genotypes failed to germinate.

## Kataribhog $\times$ Binadhan-17

The cross has been made to improve the plant's grain quality and phenotypic attributes. Partial hybrid sterility was observed in the $\mathrm{F}_{1}$ population. The mature, healthy seeds were collected from the $F_{1}$ population and raised in the Boro 2021-2022 season by following the Pedigree method. From the $\mathrm{F}_{2}$ population, the selection was based on grain quality and lodging tolerance. The selected plant progeny was grown in the subsequent Aus season. More importantly, all the $\mathrm{F}_{2}$ genotypes were preserved by collecting single panicle from each genotype and were raised in Aus following the Field RGA method.

## Black Rice

The $\mathrm{M}_{3}$ population was grown in bulk in Aman 2021-2022 season. The selection was made based on the grain attributes and tillering capacity. A total of 10 plants were selected from the $\mathrm{M}_{3}$ population. In the Boro 2021-2022, individual plant progeny was grown following the pedigree method. The selection was based on grain quality in the $\mathrm{M}_{4}$ population. The subsequent progeny was produced in the Aus 2021-2022 following the Field RGA method.

## Population screening

## Screening of upland rice lines for drought tolerance

The experiment was conducted to identify suitable rice genotypes with drought tolerance and higher grain yield. Total 25 IURON (International Upland Rice Observational Nursery) rice lines
along with five negative and positive controls were screened for drought tolerance at vegetative and reproductive stage.

The vegetative stage screening was done hydroponically in a glass house using Polyethylene Glycol (PEG) -6000. Drought was initially imposed for seven days by $10 \%$ PEG on 14 days old seedlings. With $15 \%$ PEG, a progressive drought was induced for the following seven days. The experiment ended on day 28 , and data regarding the drought were gathered. The reproductive stage screening was done in trays beneath the polythene shed. Drought was imposed for 28 days at the peak of tillering to screen the reproductive stage. At that point, the volumetric soil moisture had dropped to $3 \%$, and lifesaving irrigation had been used to recover from the drought. At $80 \%$ maturity, the experiment was harvested. Data regarding seed setting \% were gathered. RCB design with two replications was used in both instances.

The analysis employed curated data. Utilizing the following method, it was determined how much each trait was affected by drought.
$\%$ Reduction of the trait $=\frac{\text { performance of the trait in control-performance of the triat in drought }}{\text { performance of the trait in control }} \times 100$
The genotypes were ultimately divided into precise tolerance or susceptible levels based on how well they performed under drought and how satisfactory they scored during drought, according to the IRRI SES 5th edition.

The statistics illustrate how the genotypes responded to drought. The genotypes BN-UR-1014, BN-UR-1016, BN-UR-1012, BN-UR-1004, BN-UR-1005, and BN-UR-1024 performed better in terms of the percent reduction in plant height (Table 40), which indicates that these genotypes demonstrated drought tolerance for this specific character and their plant height reduction percentage was under $30 \%$. The genotypes BN-UR-1023, BN-UR-1010, BN-UR-1020, and BN-UR-1009 displayed vulnerability to drought, with plant height drop percentages ranging from $40 \%$ to $50 \%$. Other genotypes performed moderately when exposed to drought and exhibited plant height reductions between $30 \%$ and $40 \%$. Regarding this trait, the checks BRRI dhan 96 , Binadhan-17, and Binadhan-19 performed much better than the others, while BRRI dhan58 did the worst. More intriguingly, the plant height reduction percentage in this instance was 33.02 percent for the susceptible check IR-64, indicating that the global check behaved moderately.

The genotype BN-UR-1014 seemed to have the highest performance ( $2.5 \%$ ) when it came to the percent reduction in root length, followed by the genotypes BN-UR-1006 (3.64\%), BN-UR-1003 (5.61\%), BN-UR-1002 (9.57\%), BN-UR-1008 (9.75\%), BN-UR-1015 (10.40\%), and BN-UR1004 (10.62\%). BN-UR-1001 saw the greatest root length reduction (40.77\%), followed by BN-UR-1013 (38.06\%), BN-UR-1018 (36.82\%), and BN-UR-1025. (33.27\%). Root length reduction among the checks ranged from $14.30 \%$ (Binadhan-19) to $33.60 \%$ (IR-64).

Table 40: Reduction percentage in different traits in the studied genotypes

| Genotype | \% Reduction <br> in plant height | \% Reduction <br> in root length | \% Reduction <br> in rat <br> number | \% Reduction in <br> shoot <br> deight | \% Reduction in <br> root dry weight |
| :--- | :---: | :---: | :---: | :---: | :---: |
| BN-UR-1001 | 29.15 | 40.77 | 33.68 | 30.76 | 37.5 |
| BN-UR-1002 | 31.32 | 9.57 | 13.88 | 32.75 | 18.75 |

| BN-UR-1018 | 34.02 | 36.82 | 31.87 | 45.16 | 48.21 |
| BN-UR-1019 | 37.17 | 28.05 | 4.99 | 59.20 | 50.00 |
| BN-UR-1020 | 42.02 | 24.72 | 12.39 | 56.16 | -16.66 |
| BN-UR-1021 | 35.35 | 24.12 | 23.81 | 46.18 | 26.66 |
| BN-UR-1022 | 36.83 | 31.13 | -4.76 | 50.27 | 26.78 |
| BN-UR-1023 | 47.70 | 21.12 | 15.68 | 69.94 | 63.69 |
| BN-UR-1024 | 27.36 | 16.76 | -2.94 | 52.97 | 67.5 |
| BN-UR-1025 | 38.56 | 33.27 | 34.89 | 45.31 | 52.34 |
| BRRI dhan58 | 40.66 | 19.09 | -2.63 | 42.39 | 36.50 |
| BRRI dhan96 | 21.40 | 21.051 | 5.85 | 5.55 | 8.92 |
| Binadhan-17 | 26.98 | 20.26 | 42.46 | 18.55 | 23.33 |
| Binadhan-19 | 29.52 | 14.30 | 32.11 | 18.33 | 41.6 |
| IR-64 | 33.02 | 33.60 | 17.73 | 55.76 | 56.25 |
|  |  |  |  |  |  |

The genotypes BN-UR-1005, BN-UR-1022, and BN-UR-1024 produced more roots than the control condition in terms of root number (Table 1). In BN-UR-1019 and BN-UR-1004, the reduction of the root number was less than $10 \%$. However, the roots of BN-UR-1010, BN-UR-

1013, BN-UR-1008, and BN-UR-1007 were reduced by nearly $50 \%$. The experiment results showed that BRRI dhan58 and dhan96 performed better among the checks.

Shoot dry weight decreased slightly in BN-UR-1014 and BN-UR-1016 but significantly in BN-UR-1023, BN-UR-1019, BN-UR-1013, BN-UR-1020, BN-UR-1009, BN-UR-1010, and BN-UR-1011 (Table 1). However, the genotypes BN-UR-1014, BN-UR-1010, BN-UR-1004, BN-UR- 1015, and BN-UR-1020 generated higher dry root weight than the control condition. In contrast, the root weight significantly decreased in the genotypes BN-UR-1023, BN-UR-1024, BN-UR-1025, and BN-UR-1013 (Table 40). When both the shoot and root dry weights were considered, BRRI dhan96, Binadhan-17, and Binadhan-19 outperformed IR-64.

Considering the studied trait at the vegetative stage and the SES drought scoring, the genotypes were classified into tolerant, moderately tolerant, moderately susceptible, and susceptible groups (Table 41).

Table 41: Classification of rice lines for drought tolerance based on IRRI SES score

| Tolerant | Moderately tolerant | Moderately susceptible | Susceptible |
| :---: | :---: | :---: | :---: |
| BN-UR-1004 | BN-UR-1002 | BN-UR-1001 | BN-UR-1013 |
| BN-UR-1005 | BN-UR-1003 | BN-UR-1009 | BN-UR-1019 |
| BN-UR-1014 | BN-UR-1006 | BN-UR-1010 | BN-UR-1023 |
| BN-UR-1015 | BN-UR-1007 | BN-UR-1020 | BN-UR-1025 |
| Binadhan-17 | BN-UR-1008 | BN-UR-1021 | IR-64 |
| BRRI dhan96 | BN-UR-1018 | BN-UR-1022 |  |
|  | BN-UR-1011 | BN-UR-1024 |  |
|  | BN-UR-1012 |  |  |
|  | BN-UR-1016 |  |  |
|  | BN-UR-1017 |  |  |
|  | BN-UR-1018 |  |  |
|  | BRRI Dhan58 |  |  |

Binadhan-19

| Total $=6$ | Total $=13$ | Total $=7$ | Total $=5$ |
| :---: | :---: | :---: | :---: |

Different genotypes responded differently to drought when they were in the reproductive stage. Compared to control conditions, the genotypes BN-UR-1017, BN-UR-1005, and BN-UR-1015 produced more seeds. In contrast, the seed setting was drastically reduced in BN-UR-1019, BN-UR-1010, and BN-UR-1001 (Figure 4). In drought, BRRI dhan96, Binadhan-17, and Binadhan-

19 produced more seeds, whereas IR-64 suffered an almost $40 \%$ decrease in seed setting.
Figure 4: \% Reduction in seed setting in the studied genotypes.
The genotypes performed essentially the same in various developmental phases. In both the vegetative and reproductive stages, the genotypes BN-UR-1004, BN-UR-1005, BN-UR-1014, BN-UR-1015, and BN-UR-1017 can be regarded as tolerant. However, the genotypes BN-UR1013, BN-UR-1019, BN-UR-1023, and BN-UR-1025 are vulnerable to drought. The tolerant genotypes were selected for further evaluation to assess the adaptability and stability for drought tolerance under field condition.

## AGGRi Network Trial 2021 Wet Season

Rice (Oryza sativa L.) is the world's second most extensively grown cereal crop and the staple food for more than half of the world's population, particularly in Asia and Africa. The rapidly growing population is generating pressures for increasing the food production. Thus, increase in grain yield potential is the major goal of almost all rice breeding programs. But increasing yield is a major challenge as it is a complex trait and controlled by polygenes with high influence of environmental interactions. Therefore, major impacts are related to the development of new strategies to increase the genetic gain for the development of high yield potential rice varieties. On that account, a trial of IRRI developed advanced breeding lines was conducted at BINA substation Barisal to understand and select the best performing breeding lines with highest genetic merits in long duration environment of Bangladesh.

The trial was conducted with IRRI developed 188 advanced breeding lines and 12 international and local check varieties. The seeds were sown on 15 July 2021 and thirty days old seedlings were transplanted on 15 August 2021 following alpha lattice experimental design with 2 replications. The unit experimental plot size was $5.4 \mathrm{~m}^{2}$ [ 5.4 m ( 27 hills) x 1.0 m ( 4 rows)]. Twothree seedlings per hill were transplanted, maintaining a 20 cm distance between plant to plant and row to row. BRRI Transplanted Aman Recommendation SOP was followed for the crop management. All the rice plants were harvested from each plot separately, and data were recorded on days to $50 \%$ flowering, days to $80 \%$ maturity, plant height, plot yield (kg), and grain moisture content (\%). Plant height was recorded from randomly selected 5 hills of each plot. Plot yield data were adjusted to t /ha. Finally, the recorded data were tabulated and analyzed using single-environment analysis following Alpha-Lattice Design.

A wide range of variation was observed for the phenotypic developments of the tested genotypes. All the tested genotypes showed significant differences for days to $50 \%$ flowering. The days to $50 \%$ flowering ranged from 93 to 101 days (Table 1). The entry IR126952:173-AC 16-1-B and IR16F1097 had the shortest and longest flowering time, respectively.

The tested genotypes showed a wide range of variation in plant height ranged between 84 to 158 cm (Table 42). Among them, the shortest and tallest plant height was exhibited by IR 99853-B-B-B-752 and IR15F1931, respectively.

Table 42. Raw data report

| Trait | Range | Mean | Sd | CV (\%) |
| :--- | :--- | :--- | :--- | :--- |
| Days to 50\% Flowering | $93-101$ | 96.44 | 6.98 | 7.24 |
| Plant Height (cm) | $84-158$ | 115.88 | 14.89 | 12.85 |
| Yield (t/ha) | $1.9-5.6$ | 3.76 | 1.15 | 30.58 |

Sd=Standard Deviation, CV=Co-efficient of Variation
Table 43. Descriptive statistics

| Trait | Genetic Variance | Error Variance | Heritability |
| :--- | :--- | :--- | :--- |
| Days to 50\% Flowering | 9.5 | 37.75 | 0.33 |
| Plant Height (cm) | 168.52 | 35.91 | 0.90 |
| Yield (t/ha) | 0.62 | 0.58 | 0.68 |

The grain yield varied from 1.9 to 5.6 t/ha (Table 42). Some of the breeding lines were showed promising field performance with high yield potentiality. The lowest yield was found in SAN DU BAI MI HONG GU, and IR15F1921 produced the highest grain yield among the tested genotypes.

In addition, heritability is important to quantify the precision of field trials and determine the response to selection. Therefore, the heritability for days to $50 \%$ flowering, plant height, and yield were calculated as $0.33,0.90$, and 0.68 , respectively (Table 43).

Finally, based on the available dataset, IR126952-29-65-22-5-52-B, IR126952-41-58-26-4-12-53, IR15F1921, IR16F1066, IR16F1072, IR16F1144, IR16F1234, IR16T1159, IR19L1011, and IR19L1050 were selected considering yield performance (Figure 5). Besides, some of the lines would be useful for further use as a parental line.

Figure 5. Yield performance of top ten breeding lines along with their flowering time

## AGGRi Network Trial 2022 Dry Season

Rice (Oryza sativa L.) is one of the most important food crops and is the primary staple food for nearly half of the world's population. It is expected that the world population will continue to grow and exceed nine billion by 2050, which demands a nearly $70 \%$ increase in food production. The rapidly growing population is generating pressures for increasing the food production. Therefore, ensuring the food security and sustainable development of agriculture has become a key strategic concern worldwide. Thus, increase in grain yield potential is the major goal of almost all rice breeding programs. But increasing yield is a major challenge as it is a complex trait and controlled by polygenes with high influence of environmental interactions. Therefore, major impacts are related to the development of new strategies to increase the genetic gain for the development of high yield potential rice varieties. On that account, a trial of IRRI developed advanced breeding lines was conducted during dry season 2022 at BINA sub-station Barisal to understand and select the best performing breeding lines with highest genetic merits in long duration environment of Bangladesh.

The trial was conducted with IRRI developed 188 advanced breeding lines and 12 global and local check varieties. The seeds were sown on 18 December 2021 and forty-five days old seedlings were transplanted on 2 February 2022 following alpha lattice experimental design with 2 replications. The unit experimental plot size was $5.4 \mathrm{~m}^{2}$ [ 5.4 m ( 27 hills) x 1.0 m ( 4 rows)]. Two-three seedlings per hill were transplanted, maintaining a 20 cm distance between plant to plant and row to row. BRRI Transplanted Boro Recommendation SOP was followed for the crop management. All the rice plants were harvested from each plot separately, and data were recorded on days to $50 \%$ flowering, days to $80 \%$ maturity, plant height, plot yield ( kg ), and grain moisture content (\%). Plant height was recorded from randomly selected 5 hills of each plot. Plot yield data were adjusted to t /ha. Finally, the recorded data were tabulated and analyzed using single-environment analysis following Alpha-Lattice Design.

A wide range of variation was observed for the phenotypic developments of the tested genotypes. All the tested genotypes showed significant differences for days to $50 \%$ flowering. The days to $50 \%$ flowering ranged from 101 to 147 days (Table 43). The entry SAN DU BAI MI HONG GU and IR 126952-29-65-16-2-10-B had the shortest and longest flowering time, respectively.

The tested genotypes showed a wide range of variation in plant height ranged between 76 to 153 cm (Table 43). Among them, the shortest and tallest plant height was exhibited by IR16L1886 and IR 126953:192-AC 74-1-B, respectively.
Table 43. Raw data report

| Trait | Range | Mean | Sd | CV (\%) |
| :--- | :--- | :--- | :--- | :--- |
| Days to 50\% Flowering | $101-147$ | 121 | 7.93 | 6.55 |
| Plant Height (cm) | $76-153$ | 108.83 | 13.13 | 12.06 |
| Yield (t/ha) | $0.5-7.5$ | 4.09 | 1.22 | 29.82 |

Sd=Standard Deviation, CV=Co-efficient of Variation
Table 44. Descriptive statistics

| Trait | Genetic Variance | Error Variance | Heritability |
| :--- | :--- | :--- | :--- |
| Days to 50\% Flowering | 49.58 | 13.44 | 0.88 |
| Plant Height (cm) | 101.57 | 69.6 | 0.74 |
| Yield (t/ha) | 0.79 | 0.71 | 0.69 |

The grain yield varied from 0.5 to 7.5 t /ha (Table 43). Some of the breeding lines were showed promising field performance with high yield potentiality. The lowest yield was found in IR 129462-B-46-B-1-1, and IR 126972-B-12-4-2-1 produced the highest grain yield among the tested genotypes.

In addition, heritability is important to quantify the precision of field trials and determine the response to selection. Therefore, the heritability for days to $50 \%$ flowering, plant height, and yield were calculated as $0.88,0.74$, and 0.69 , respectively (Table 44). Finally, based on the available dataset for yield performance top 20 lines including IR 99853-72-4-2-1, IR16T1159, IR $126975-B-40-3-5-2$, IR 126972-B-12-4-2-1 and IR17L1041 were selected for stage 2 trial as well as to be used in breeding program as parental lines.

## Screening advanced rice mutants for higher salt tolerance

Thirty-five rice mutants were developed from Binadhan-7 and FL-478 to select desirable mutants for higher salt tolerance. This experiment was conducted Boro season, 2021-22 at farmers field of Shyamnagar. From them a total of ten lines have been selected for further generations.

## Screening dual tolerant rice lines

Twenty rice lines were developed from Binadhan-11 and Binadhan-23 to select desirable mutants for dual tolerance (salinity and submergence). This experiment was conducted Aman season, 2021 at farmers field of Barisal. From them a total of ten lines have been selected for further generations.

## Growing $\mathrm{BC}_{3} \mathrm{~F}_{4}$ population for drought tolerance

In Boro 2021-22, the seeds of 15 selected $\mathrm{BC}_{3} \mathrm{~F}_{5}$ plants derived from crossing between Binadhan- $11 \times$ NERICA-4 were sown on 22 December, 2020 at experimental fields were set at the Plant Breeding Division, BINA, Mymensingh.Another Binadhan- $17 \times$ NERICA- 4 combination, selected $\mathrm{BC}_{3} \mathrm{~F}_{5} 15$ lines were sown on same date and same place in plant progeny rows. All the plants were selfed and harvested $\mathrm{BC}_{3} \mathrm{~F}_{5}$ seeds.

## Growing of $M_{4}$ populations of rice cultivars for earliness and higher yield

To select high yielding premium quality, the seeds of irradiated populations derived from Noor Basmoti were sown $25^{\text {th }}$ July 2021 and transplanted on $31^{\text {th }}$ August at BINA Headquarter farm, Mymensingh along with the parent. The experiment followed non replicated design with the spacing 15 cm and 20 cm . Recommended doses of nitrogen, phosphorus, potassium, sulphur and zinc were applied in the form of Urea, TSP, MoP, Gypsum and Zinc Sulphate. Cultural and intercultural practices were followed as and when necessitated. Based on earliness, plant height, grain quality 50 individual plants have been selected and will be grown in next aman season.

## Growing $M_{4}$ generation of coastal rice landraces for salt tolerance

A large number of $\mathrm{M}_{5}$ populations from Nonabokra, Mondeshore, Ghunshi, Holdegotal and Dhakshail (from three different doses) were grown in plant progeny rows for selecting desirable mutant at BINA Headquarters farm, Mymensingh during Aman season 2021. From them a total of 30 plants have been selected for future selection in subsequent generations.

## Growing $\mathbf{M}_{\mathbf{3} \text { generation of re re for drought tolerance }}$

Seeds of Binadhan-17, Binadhan-19 and NERICA-10 were irradiated with ${ }^{60} \mathrm{Co}$ gamma rays. Irradiation doses were 200, 250, 300, 350, 400, 450, 475 and 500 Gy . A large number of $\mathrm{M}_{3}$ generation were grown in plant progeny rows for selecting desirable mutant at BINA Headquarters farm, Mymensingh during Aman season 2021. From them a total of 20 plants have been selected primarily for future selection in $\mathrm{M}_{4}$ generation.

## Growing $\mathrm{M}_{\mathbf{2}}$ generation of rice for higher yield and earliness

To create genetic variability, seeds of Nepali Swarna were irradiated with 100, 150, 200, 250, 300 and 350 Gy of gamma rays. Experiment was carried out during Aman and Boro season 2021-2022. The experiment was followed by non-replicated design and sown separately as dose wise. Recommended doses of nitrogen, phosphorus, potassium, sulfur and zinc were applied in the form of Urea, TSP, MoP, Gypsum, Zinc Sulphate. Cultural and intercultural practices were followed as when necessitated. Based on earliness, plant height and grain quality 32 mutants have been selected for next generation.

Growing of M5 populations of Noor Basmati for earliness and higher yield
To select high yielding premium quality, the seeds of irradiated populations derived from Noor Basmoti were sown $25^{\text {th }}$ July 2021 and transplanted on $20^{\text {th }}$ August at BINA Substation farm, Cumilla along with the parent. The experiment followed RCB design with two replications. The size of a unit plot was $1.0 \mathrm{~m} \times 1.0 \mathrm{~m}$. Plant to plant distance was 15 cm and row to row distance was 20 cm . Recommended doses of nitrogen, phosphorus, potassium, sulphur and zinc were applied in the form of Urea, TSP, MoP, Gypsum and Zinc Sulphate. Cultural and intercultural practices were followed as and when necessitated. Data on plant height (cm), number of effective tiller plant ${ }^{-1}$, panicle length (cm) and number of filled grains panicle ${ }^{-1}$ were recorded after harvesting from 5 randomly selected competitive hills. Days to $50 \%$ flowering and days to maturity were assessed plot basis. Recorded data were finally subjected to proper statistical analyses and are presented in Table 45.

Table 45. Mean performance of M5 rice mutants with parent during aman season 2021

| Lines/ variety | Plant Height (cm) | Total tillers plant ${ }^{-1}$ (no.) | Effective tillers <br> plant ${ }^{-1}$ <br> (no.) | Panicle length (cm) | Filled grains panicle ${ }^{-}$ (no.) | Unfilled grains panicle ${ }^{-1}$ (no.) | Days to maturity | Grain yield plant ${ }^{-1}$ <br> (g) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Noor Basmati | 122.6 | 18 | 17.2 | 29.8 | 102.68 | 82.44 | 126 | 10.18 |

| 300-P1 | 131.7 | 17.1 | 15.7 | 30.4 | 72.66 | 183.42 | 117 | 7.41 |
| 300-P2 | 122.4 | 16.1 | 15.6 | 29.7 | 102.62 | 169.14 | 117 | 7.25 |
| 300-P3 | 130.5 | 15.5 | 15.5 | 27 | 102.32 | 150.61 | 117 | 5.51 |
| 300-P5 | 129.5 | 14 | 14 | 27 | 102.32 | 150.61 | 118 | 6.97 |
| 250-P1 | 123.8 | 15.6 | 15.3 | 31.2 | 180.40 | 73.20 | 125 | 9.21 |
| 250-P4 | 112.3 | 13.7 | 12.7 | 31 | 172.30 | 81.10 | 117 | 14.03 |
| 250-P5 | 118.7 | 13 | 12.8 | 33.1 | 178.70 | 70.80 | 117 | 15.43 |
| 250-P6 | 113.5 | 14.5 | 14.5 | 31 | 207.20 | 61.30 | 117 | 14.05 |
| 250-P9 | 122 | 10.5 | 9.5 | 30.2 | 124.40 | 127.70 | 132 | 11.36 |
| Maximum | 145.75 | 18 | 17.2 | 33.25 | 377.2 | 191.3 | 135 | 24.63 |
| Minimum | 96.3 | 9.5 | 9.5 | 15.1 | 72.66 | 37.7 | 102 | 5 |
| SD | 11.29 | 2.01 | 1.97 | 3.30 | 61.93 | 5.54 | 9.14 | 4.54 |

Days to maturity of the mutants and parent ranged from 102-135 days and 350-EP4, 350-EP5 took the shortest time to mature and 350-P5 took the longest time to mature. Plant height ranged between 96.3 cm to 145 cm with $350-\mathrm{EP} 3$ being the shortest and $350-\mathrm{P} 10$ the tallest. Number of eeffective tillers plant ${ }^{-1}$ ranged 9.5 to 17.2 with the parent being highest and $350-\mathrm{P} 5$ being the lowest. Panicle length ranged from 15.1 cm to 33.25 cm with the mutant $350-\mathrm{P} 4$ being longest and $350-E P 3$ being the shortest. Filled grains per panicle ranged between 72.66 to 377.2 with the mutant $350-\mathrm{P} 12$ being highest and $350-\mathrm{EP} 10$ being lowest. Grain yield plant ${ }^{-1}(\mathrm{~g})$ ranged from 524.63 g with the $350-\mathrm{P} 3$ produced highest yield while $350-\mathrm{P} 9$ being lowest.

Based on early maturity 20 mutant lines had selected and will be evaluated in the preliminary yield trial.

## Growing of $\mathrm{M}_{4}$ generations of BR22, BRRI dhan71, BRRI dhan76 and BRRI dhan77

Efforts were made to develop varieties with multiple traits viz. seedling emergence, vigorous growth, short duration (90-100 days), tolerance to lodging, medium bold to medium slender grains and good eating quality. Four popular rice varieties were irradiated with five gamma doses. A total of 96 individuals were selected from $\mathrm{M}_{3}$ generation during T. Aman, 2021 based on identical flowering, grain type traits and phenotypic acceptability under field condition.Seeds of $\mathrm{M}_{4}$ mutant of BR22, BRRI dhan71, BRRI dhan76 and BRRI dhan77 were sown on 14 July, 2021 and transplanted on 17 August 2021 at BINA Headquarter, Mymensingh by maintaining plant to plant and row to row distance 15 cm and 20 cm respectively. The experiment was followed by non- replicated design. The size of the unit plots were $1 \mathrm{~m} \times 2 \mathrm{~m}$. Recommended doses of nitrogen, phosphorus, potassium, sulphur and zinc were applied in the form of Urea, TSP, MoP, Gypsum and Zinc Sulphate. Cultural and intercultural practices were followed as and when necessitated. Data on plant height, number of effective tillers plant ${ }^{-1}$, panicle length, and filled and unfilled grains panicle ${ }^{-1}$ were recorded after harvest from 5 randomly selected competitive plants. Maturity was assessed plot basis. Finally, all the recorded data were subjected to proper statistical analyses as per design used and are presented in Table 46.

Table 46. Grain yield and yield components of $M_{4}$ generations of BR22 that were sown at BINA Headquarter, Mymensingh

| Variety/Mutant | Duration | Plant <br> height $(\mathrm{cm})$ | Effective <br> Tiller | Panicle <br> length $(\mathrm{cm})$ | Filled <br> grain | 1000 seed <br> wt. $(\mathrm{g})$ |

Significant variation was observed in term of duration among the mutants. Mutant line BRM22-350-17 had shorter duration ( 135 days). All the mutant lines had lower effective tillers comparing to the check variety BR22 (13). In BRM22-200-17, BRM22-250-27, BRM22-350-14 and BRM22-350-31 had longest Panicle length ( 31 cm ). The mutant line BRM22-350-35 had highest number (190) of filled grains panicle ${ }^{-1}$ contrasting to other mutant lines and the check variety BR2 (112). Highest 1000 seed weight (22.5) was observed in BRM22-350-3 mutant line comparing to the check variety BR22 (20.3) and other mutants (Table 47-50).

Significant variation was observed in term of duration among the mutants. Mutant line BRM71-200-4 had longer duration (124 days). The mutant line BRM71-200-6 had higher effective tillers comparing to the check variety BRRI dhan71 (11). In BRM71-350-6 mutant line had longest Panicle length ( 30 cm ). The mutant BRM71-350-4 had highest number (177) of filled grains panicle ${ }^{-1}$ contrasting to other mutant line and the check variety BRRI dhan71 (105). Highest 100 seed weight (22.5) was observed in BRM71-200-4 mutant line comparing to the check variety BRRI dhan71 (23.9) and other mutants (Table 47).

Significant variation was observed in term of duration among the mutants. The mutant line BRM76-350-6 had shorter plant height ( 136 cm ). The mutant line BRM76-300-5 had higher effective tillers comparing to the check variety BRRI dhan76 (8). In BRM76-350-8 mutant line had longest Panicle length ( 33 cm ). The mutant line BRM76-350-3 had highest number (212) of filled grains panicle ${ }^{-1}$ contrasting to other mutant line and the check variety BRRI dhan76 (140). Highest 1000 seed weight (29) was observed in BRM76-250-1 mutant line comparing to the check variety BRRI dhan76 (25.6) and other mutants (Table 48).

| BRM77-350-17 | $140 \pm 0.67$ | $145 \pm 1.24$ | $12 \pm 0.73$ | $31 \pm 0.73$ | $125 \pm 6.48$ | $31.4 \pm 0.54$ |
| BRRI dhan77(p) | $147 \pm 0.67$ | $147 \pm 1.24$ | $9 \pm 0.73$ | $26 \pm 0.73$ | $115 \pm 6.48$ | $27.3 \pm 0.54$ |

Significant variation was observed in term of duration among the mutant lines. Mutant line BRM77-350-12 had shorter plant height ( 126 cm ). The mutant line BRM77-300-13 and BRM77-350-13 had higher (17) effective tillers comparing to the check variety BRRI dhan77 (9). In BRM77-300-8, BRM77-350-12, BRM77-350-14 mutant line had longest Panicle length ( 32 cm ). The mutant line BRM77-300-8 and BRM77-300-12 had highest number (200) of filled grains panicle ${ }^{-1}$ contrasting to other mutant line and the check variety BRRI dhan77 (115). Highest 100 seed weight (31.9) was observed in BRM77-350-16 mutant line comparing to the check variety BRRI dhan77 (27.3) and other mutant (Table 49).

Considering the yield \& yield attributes, the promising lines will be evaluated for the next generation.

## Evaluation of $\mathbf{M}_{6}$ generation of rice for short duration, premium quality and higher yield

Every rice improvement program strives to replace low-yielding, high-quality with high-yielding varieties. To date, rice breeders have generally failed to combine high yields with optimal quality because not all quality traits are defined. Quality evaluation programs have been measuring the same traits for many decades, and current tools of evaluating grain quality cannot distinguish an old variety from a potential replacement, though consumers are readily able to do so. The objective of this experiment is to find out the rice lines higher yield coupled with the qualitative attribute such as slender grain and preferable to the consumers.

The seeds of $\mathrm{M}_{3}$ generation of LIRG-2 and LIRG-4 were sown on 12 December, 2021 and transplanted on 24 January, 2021 at BINA Headquarter field by maintaining Plant to plant and row to row distance 20 cm and 15 cm respectively. The experiment was followed by non replicated design. A unit plot size was $2 \mathrm{~m} \times 1 \mathrm{~m}$. Recommended doses of nitrogen, phosphorus, potassium, sulphur and zinc were applied in the form of Urea, TSP, MoP, Gypsum and Zinc Sulphate. Cultural and intercultural practices were followed as and when necessitated. Data on plant height, effective tiller hill ${ }^{-1}$, panicle length, filled and unfilled grains panicle ${ }^{-1}$ and grain yield hill ${ }^{-1}$ was recorded from randomly selected five competitive hills at maturity. Maturity was assessed pot basis.

Significant variation was observed in term of duration among the mutants. Mutant LIRG-217Seg P-1, LIRG-4 Seg-1(1)-2 and LIRG-4 Seg-1 (AL) had shorter duration (140 days, 142 days and 142 days respectively). Although the mutants had lower no. of effective tillers comparing to the check variety BRRI dhan29 (8.8) but because of long panicle and higher no. of filled grain some mutants performed better over the check. Longest Panicle length ( 30.8 cm ) was observed in L4-P-1-2 mutant. The mutant L4-P-3(2)-P-1 had highest number (342) of filled grains panicle ${ }^{-}$ ${ }^{1}$ contrasting to other mutants and the check variety BRRI dhan29 (106). Lowest unfilled grains
paicle ${ }^{-1}$ (28.4) was observed in the mutant L4-P-4(1)-P-3. The mutants L4-P-6(3)-1, LIRG-2-Seg-1-P-2, L4-P-4(1)-P-2, and LIRG-2-17Seg P-1 exhibited higher yield (9.58, 8.21, 8.01 and $7.42 \mathrm{ton} / \mathrm{ha}$ respectively) than the other mutants and the check variety BRRI dhan29 (5.28 t/ha) (Table 50).

Considering the yield \& yield attributes, the promising mutants will be evaluated for the next generation

## Growing of $\mathrm{BC}_{1} \mathbf{F}_{5}$ generation of Binadhan- $18 \times$ Luxmidigha cross

The deep water rice cv, Luxmidigha is cultivated in the low laying areas in Bangladesh where water stand up to 3 months. It has broad leaves with stem elongation (>5cm/day) ability, knee capacity and floatability. However, this cultivar is not well practiced now-a days due to its low yield (0.7-1.0 ton/ha). To introgress the characteristics of luxmidigha to the recipient parent and form a backcross family by which desirable characteristics can be attained in $\mathrm{F}_{2}$ progenies have been observed in several studies. Several morphological traits, such as height of the plant, floatability, stem elongation can be found among the progenies of a single cross. Many traditional transplanting Aman rice varieties do not have these special traits and unable to survive in this deep water table. The present study was undertaken to evaluate the morpho-physiological, agronomic \& yield performances of backcross families that will accelerate chance of obtaining desirable lines.
The seeds of $15 \mathrm{BC}_{1} \mathrm{~F}_{4}$ populations derived from crossing between Laksmi digha and Binadhan18 were sown on 31 July, 2021 and transplanted on 13 November at BINA HQs farm, Mymensingh. The parents were also included in this experiment by maintaining plant to plant and row to row distance 15 cm and 20 cm respectively. The experiment was conducted by following non replicated design. A unit plot size was $2 \mathrm{~m} \times 1 \mathrm{~m}$. Recommended doses of nitrogen, phosphorus, potassium, sulphur and zinc were applied in the form of Urea, TSP, MoP, Gypsum and Zinc Sulphate. Cultural and intercultural practices were followed as and when necessitated. Data on plant height, effective tiller, panicle length, filled and unfilled grains panicle ${ }^{-1}$ and grain yield hill $^{-1}$ was recorded from randomly selected five competitive hills at maturity. Maturity was assessed pot basis. The recorded data were finally subjected to proper statistical analysis and are presented in Table 51.

Most of the lines had significantly shorter plant height than the parent Laksmi digha (Table 51). The line RC-2-4-7-3-6 had the highest plant height ( 145 cm ) comparing to the other lines. Number of effective tiller was highest in the RC-1-6-1-3-5 line (15.4) Table 51). The line RC-2-6-3-1-8 had significantly higher number of filled grains panicle ${ }^{-1}$ (135) than other progenies. The line RC-4-1-15-2-11 had highest grain yield ( 22.6 g plant $^{-1}$ ) than the other lines and parents. All these high yielding crossing lines with Luxmidigha (parent) will be screened in Deep water Rice Screening Tank (DWRST) to check the floatability, stem elongation ability in the next growing season (Table 51).
Considering the yield \& yield attributes, the promising lines will be evaluated for the next generation.

## Evaluation of backcross population ( $\mathrm{BC}_{1} \mathrm{~F}_{5}$ ) crossing Binadhan-17 with Monjusree-2 and Chandanath-3

Cold injury is one of the prime abiotic factors which reduce rice yield in several countries. In Bangladesh, Boro paddy is the main crop of the haor people. Boro season usually begins in midNovember but many farmers start sowing in late October to avoid flash floods. As a result, the harvesting time fall sometime in January-February triggers yield loss due to cold stress. Percentage of germination, poor seedling establishment, yellowing of the leaves, growth retardation, and decreased tillering is the symptoms caused by cold stress. The objectives of this study are to screen high yielding cold-tolerant rice cultivars through backcross breeding and cold tolerance can be traced by the molecular breeding approach to strengthen food security to the next generations
The seeds of $\mathrm{BC}_{1} \mathrm{~F}_{5}$ populations derived from crossing between Binadhan-17 with Monjusree-2 and Chandanath-3 were sown on 02 December, 2021 and transplanted on 15 January 2022 at BINA Headquarter field by maintaining Plant to plant and row to row distance 20 cm and 15 cm respectively. The parents were also included in this experiment. The experiment was followed by non replicated design. A unit plot size was $2 \mathrm{~m} \times 1 \mathrm{~m}$. Recommended doses of nitrogen, phosphorus, potassium, sulphur and zinc were applied in the form of Urea, TSP, MoP, Gypsum and Zinc Sulphate. Cultural and intercultural practices were followed as and when necessitated. Data on plant height, total tiller hill ${ }^{-1}$, effective tiller hill ${ }^{-1}$, panicle length, filled and unfilled grains panicle ${ }^{-1}$ and grain yield hill ${ }^{-1}$ was recorded from randomly selected five competitive hills at maturity. Maturity was assessed pot basis.

All the lines had statistically significant variation in plant height (Table 52). Significant statistical variation was observed in effective tiller among the lines. The line RM-M2-P-15 and RM-M2-P-8 exhibited longer panicle length ( 27.2 cm ) and higher filled grains/panicle (179) respectively comparing to the both parents. The line RM-C3-P-1 showed significantly maximum unfilled grains/panicle (72) comparing to the parent. The line RM-M2-P-8 had higher yield (8.6 $\mathrm{t} / \mathrm{ha}$ ) comparing to the parents (Table 52).
Considering the yield \& yield attributes, the promising lines will be evaluated for the next generation

## Evaluation of backcross population ( $\mathrm{BC}_{1} \mathrm{~F}_{5}$ ) crossing Binadhan-17 with Kamol-7 and Kamol-9

The seeds of $\mathrm{BC}_{1} \mathrm{~F}_{5}$ populations derived from crossing between Binadhan- 17 with Kamol-7 and Kamol-9 were sown on 02 December, 2021 and transplanted on 11 January, 2022 art BINA Headquarter field by maintaining Plant to plant and row to row distance 20 cm and 15 cm respectively. The parents were also included in this experiment. The experiment was followed by non replicated design. A unit plot size was $2 \mathrm{~m} \times 1 \mathrm{~m}$. Recommended doses of nitrogen, phosphorus, potassium, sulphur and zinc were applied in the form of Urea, TSP, MoP, Gypsum and Zinc Sulphate. Cultural and intercultural practices were followed as and when necessitated. Data on plant height, effective tiller hill ${ }^{-1}$, panicle length, filled and unfilled grains panicle ${ }^{-1}$ and grain yield hill ${ }^{-1}$ was recorded from randomly selected five competitive hills at maturity. Maturity was assessed pot basis.

In Mymensingh, All the line had statistically significant variation in plant height Table 53). Significant statistical variation was observed in effective tiller among the lines. The line RM-K7-P-9 exhibited longer panicle length ( 26.1 cm ) and higher filled grains/panicle (178) respectively comparing to the parents. The line RM-K9-P-3 showed significantly maximum unfilled grains/panicle (63) comparing to the parent. All the line including RM-K9-P-3 had higher yield ( $7.8 \mathrm{t} / \mathrm{ha}$ ) comparing to the parents (Table 53).
Considering the yield \& yield attributes, the promising lines will be evaluated for the next generation.

## Evaluation of short duration and cold tolerant rice lines suitable for haor and northern area

The seeds of backcross populations were sown on 17-24 October, 2021 and transplanted at 12-25 November at BINA Headquarter, Rangpur and Sunamganj Substation by maintaining plant to plant and row to row distance 20 cm and 15 cm respectively. The parents were also included in this experiment. The experiment was followed by non replicated design. A unit plot size was 2 m $\times 1 \mathrm{~m}$. Recommended doses of nitrogen, phosphorus, potassium, sulphur and zinc were applied in the form of Urea, TSP, MoP, Gypsum and Zinc Sulphate. Cultural and intercultural practices were followed as and when necessitated. Data on plant height, effective tiller hill ${ }^{-1}$, panicle
length, filled and unfilled grains panicle ${ }^{-1}$ and grain yield hill ${ }^{-1}$ was recorded from randomly selected five competitive hills at maturity. Maturity was assessed pot basis.

In Mymensingh, All the lines had statistically significant variation in plant height (Table 54). The line RM-16 had shorter plant height ( 70.8 cm ) comparing to other lines. Highest effective tiller (28.2) was observed in the RM-90 line. Significant statistical variation was observed in panicle length among the lines. In addition, longer panicle length ( 29.66 cm ) was found in the

RM-60 line. The lines RM-90 and RM-60 showed highest yield (15.84 and $15.12 \mathrm{t} / \mathrm{ha}$ respectively) comparing to the other mutants (Table 54).
Table 55. Grain yield and yield components of some mutants were sown at BINA substation, Sunamganj

In Sunamganj, All the line had statistically significant variation in plant height (Table 55). The line RM-2 had shorter plant height ( 74 cm ) comparing to other population. Highest effective tiller (25.6) was observed in the RM-39 line. Significant statistical variation was observed in panicle length among the lines. In addition, longer panicle length ( 26.66 cm ) was found in the

RM-27 lines. The lines RM-39 and RM-114 showed highest yield (15.1 and 13.51 t/ha respectively) comparing to the other mutants. (Table 55).

In Rangpur, All the lines had statistically significant variation in plant height (Table 56). The line RM-82 had shorter plant height ( 69.8 cm ) comparing to other progenies. Highest effective tiller (47.2) was observed in the RM-99 line. Significant statistical variation was observed in panicle length among the lines. In addition, longer panicle length ( 25.2 cm ) was found in the RM-53 line. Highest filled grain/panicle (98.4) was found in RM-115 line. The line RM-120 showed highest yield (14.1 t/ha respectively) comparing to the other lines (Table 56)
Considering the yield \& yield attributes, the promising lines will be evaluated for the next generation

## Evaluation of $\mathrm{BC}_{3} \mathrm{~F}_{6}$ population derived from Binadhan-14

Varieties with moderate shattering are favored where rice is harvested by large combined harvester-threshers, while harvesting using a small head-feeding combine is most efficient when hard-shattering to non shattering varieties are used. Farmers who harvest and thresh rice by hand prefer moderate-shattering varieties, similar to those used in the most heavily mechanized systems. Easy-shattering varieties are not acceptable to any of the farmers because they cause severe yield loss no matter what type of harvesting is practiced. Shattering also causes unexpected mixing of varieties due to germination of shattered seeds in rice fields, resulting in deterioration of rice quality

The seeds of backcross populations were at BINA Headquarter, Mymensingh on 5 December, 2021 and transplanted on 5 January, 2022 by maintaining plant to plant and row to row distance 20 cm and 15 cm respectively. The parents were also included in this experiment. The experiment was followed by non replicated design. A unit plot size was $2 \mathrm{~m} \times 1 \mathrm{~m}$. Recommended doses of nitrogen, phosphorus, potassium, sulphur and zinc were applied in the form of Urea, TSP, MoP, Gypsum and Zinc Sulphate. Cultural and intercultural practices were followed as and when necessitated. Data on plant height, effective tiller hill ${ }^{-1}$, panicle length, filled and unfilled grains panicle ${ }^{-1}$ and grain yield hill ${ }^{-1}$ was recorded from randomly selected five competitive hills at maturity. Maturity was assessed pot basis.

Table 57. Grain yield and yield components of $\mathrm{BC}_{3} \mathrm{~F}_{1}$ population derived from Binadhan-14

Significant variation was observed in term of plant height among lines. The line B-P-5-1-2 had taller plant height (102.47) comparing to the parent Binadhan-7, Binadhan-14 and Binadhan-28. The line B-P-1-1-1 had higher effective tillers (14.07) comparing to the other lines. In B-P-5-1-2 backcross population, longest Panicle length $(25.27 \mathrm{~cm})$ was found. The two lines B-P-2-1-1 and B-P-3-3-1 took comparatively less time (138 days and 139 days) to get $80 \%$ maturity comparing to the other progenies. Higher 1000 seed weight ( 24.67 gm .) was found in B-P-2-2-2 line comparing to the check variety Binadhan-7, Binadhan-14 and BRRI dhan28. The line B-P-5-1-2 gave higher yield 8.45 ton/ha comparing to the check variety Binadhan-7 ( $7.20 \mathrm{t} / \mathrm{ha}$ ), Binadhan14 ( $6.48 \mathrm{t} / \mathrm{ha}$ ) and BRRI dhan28 ( $6.62 \mathrm{t} / \mathrm{ha}$ ) respectively (Table 57). Considering the yield \& yield attributes, the promising lines will be evaluated for the next generation

## Hybrid Rice

## Source Nursery and Test cross Nursery

The source nursery was constructed with the mutant CMS line SQR-6 (Figure 5) and other 20 Aman season variety/advanced lines. Eighteen successful test crosses were made, and the test cross hybrids were used to construct the test cross nursery. In the following Boro 2021-2022 season, the test cross hybrids were evaluated for maintenance or restoring capacity. The results showed that among the pollen parents, Binadhan-17 and MAGIC-62-2 had the restoring ability

## Handling of Mutant population for hybrid rice

Seeds of Binadhan-16 and Binadhan-17 were irradiated with 250 Gy of gamma ray. The $\mathrm{M}_{1}$ population was grown with closed spacing. After maturity the seeds were harvested by picking single healthy panicle from each plant.

## Resistant Breeding of Rice Blast:

Introgression blast resistant genes Piz, Pi2, Pi9 derived from Pongsu Seribu 2 into Binadhan 17 through marker-assisted backcrossing

## Marker-assisted foreground selection

For the development of blast resistant rice variety, the $\mathrm{F}_{1}$ generations derived from cross between Binadhan-17 and blast resistant rice variety Pongsu Seribu-2, were evaluated for hybridity using the Piz, Pi2, Pi9 and Piz linked molecular markers RM6836 and RM8225 (Table 59) in Aman 2018-2019. $\mathrm{F}_{1}$ was backcrossed with Binadhan-17 to generate $\mathrm{BC}_{1} \mathrm{~F}_{1}$ population. $100 \mathrm{BC}_{1} \mathrm{~F}_{1}$ seeds were grown in pot in Aman, 2019-2020. $\mathrm{BC}_{1} \mathrm{~F}_{1}$ plants have been confirmed using blast resistant linked gene markers (RM8225 and RM6836). Rest of the plants were discarded. Based on highest recipient parent recovery ( RPG ), four $\mathrm{BC}_{1} \mathrm{~F}_{1}$ plants were backcrossed with Binadhan17 to generate $\mathrm{BC}_{2} \mathrm{~F}_{1}$ population. $150 \mathrm{BC}_{2} \mathrm{~F}_{1}$ seeds were grown in pot in Aman, 2020-2021. In the $\mathrm{BC}_{2} \mathrm{~F}_{1}$ generation, plants having the genes Piz, Pi2, Pi9 and Piz have been confirmed using blast resistant linked gene markers (RM8225 and RM6836). Rest of the plants were discarded. Based on highest recipient parent recovery (RPG), four $\mathrm{BC}_{2} \mathrm{~F}_{1}$ plants were forwarded to generate the $\mathrm{BC}_{2} \mathrm{~F}_{2}$ and $\mathrm{BC}_{2} \mathrm{~F}_{3}$ population in 2021-2022. BINA-BR-4-10-18, BINA-BR-4-10-12, BINA-BR-4-10-15 and BINA-BR-4-10-19 lines were selected from $\mathrm{BC}_{2} \mathrm{~F}_{3}$ population. All foreground selections are shown in Figure 7.

$76.9 \%$ respectively. In the backcross generation $\mathrm{BC}_{2} \mathrm{~F}_{1}$, best four plants had been selected based on the highest genome recovery i.e; $82.4,89.4,86.8$ and $92.9 \%$ respectively. The number of polymorphic markers per chromosome ranged from four to six. Chromosome 6 contained the Piz, Pi2, Pi9 and Piz genes, (Fig. 8). All of the chromosomes were fully recovered in all of the improved lines except for the region carrying the resistance genes on chromosome 6 (Fig. 9). The greatest recovery ratio of the RPG was $96.1 \%$ in BINA-BR-4-10-12 (Fig. 10) and $94.3 \%$ in BINA-BR-4-10-19.

## Diversity of rice blast pathogen (Pyricularia oryzae) in Bangladesh

## Collection, isolation and Preservation of blast isolates

In total, 120 blast isolates (Pyricularia oryzae) were collected from the infected leaves and panicles of 12 rice ( $O$. sativa L.) cultivars, including high- yielding inbred lines, and hybrid rice of Mymensingh, Rangpur, Sylhet divisions in Bangladesh. Sampling will be covered all of the administrative divisions of Bangladesh. Single spores were isolated from infected leaves or panicles incubated on moist filter paper in a petri dish at room temperature for 24 h in accordance with the protocols of Hayashi et al. (2009). Colonies from single conidia were grown on water agar for 5 to 7 days; two or three cut pieces of single colony were then transferred to sterile filter paper placed on water agar medium. Finally, to enable repeated access to the original isolates, the fungi were grown on filter paper and 20 isolates were stored aseptically in filter paper at $-20^{\circ} \mathrm{C}$ after the necessary drying for the study of morphological, molecular and pathogenocity test. Total activities are shown in Figure11.

observation under (D) Single Conidia transfer into water agar medium (E) Single Conidia Germination and single colony advancement (F) Morphological differentiation of blast isolates on potato sucrose agar medium

## Wheat

## Preliminary yield trial with one high yielding wheat mutants

Among the abiotic stresses, drought is the most prominent and prevalent limiting factors of wheat production (Daryanto et al, 2016; Zhang et al, 2018; Sarto et al, 2017). Rising temperature and changing in precipitation pattern lead to increasing incidence and intensity of drought events in country like Bangladesh (Shahid et al, 2016). Drought employs expressively adverse effects on production of winter crop wheat in northern and central part of Bangladesh (Abhinandan, et al, 2018). Around 3.5 million ha land is vulnerable to crop production due to drought and wheat is one of the major cereal crops under the radar of this threat (Alam K, 2014). Considering these facts, drought should be highly preferred in future wheat improvement programs. For attaining self-sufficiency in wheat production, wheat breeders of Bangladesh have no alternatives but to develop well adapted drought tolerant
varieties (Hossain et al; 2013). There are ample opportunities to increase drought tolerance of wheat through making some alterations in genetic through mutation breeding.

The experiment was conducted to screen the line that will be high yielding in all wheat growing areas including Barind area so that wheat demand in these areas can be alleviated rigorously.

Seeds of BWM-M-1-1 and the check variety BARI Gom-28 were sown at BINA Headquarter, Mymensingh, BINA substation Rangpur, BINA substation Khagrachari and BINA substation Chapainawabganj by maintaining plant to plant and row to row distance 15 cm and 20 cm respectively. The experiment was followed by RCB with 3 replications. The size of the unit plots were $3.0 \mathrm{~m} \times 4.0 \mathrm{~m}$. Recommended doses of nitrogen, phosphorus, potassium, sulphur, zinc and boron were applied in the form of Urea, T.S.P, MOP, Gypsum, Zinc sulphate and Boric acid. Cultural and intercultural practices were followed as and when necessitated. Data on Days to first flowering, days to $50 \%$ flowering, days to maturity, plant height, number of tillers plant ${ }^{-1}$, number of effective tillers plant ${ }^{-1}$, spikelet length, number of filled grains spikelets ${ }^{-1}, 1000$-seed weight, grain yield tha ${ }^{-1}$.were recorded after harvest from 5 randomly selected competitive plants. Maturity was assessed plot basis. Finally, all the recorded data were subjected to proper statistical analyses as per design used and are presented in Table 60.
Table 60. Yield and yield components of wheat mutants with check varieties at different locations

Results showed significant variation among the mutants and check for most of the characters in individual and over locations in combined analysis. From combined analysis, it was observed that plant height of the line BWM-M-1-1 were 85.16 cm which is statistically taller than the check variety BRRI Gom-28 ( 83.11 cm ). The line BWM-M-1-1 had statistically higher number of effective tillers 9.48 comparing to BARI Gom-28 (8.13). Spike length of BWM-M-1-1 was recorded as 9.15 which are statistically higher than check variety BARI Gom-28 (8.38). The highest number of filled grains panicle ${ }^{-1}$ was observed BWM-M-1-1 (52.65) followed by BARI Gom-28 (46.87). Check variety BRRI Gom-28 had statistically higher number of 1000 grain weight ( 47.24 g .) to the BWM-M-1-1 line ( 45.22 g .). The line BWM-M-1-1 had produced higher yield ( 3.81 tha $^{-1}$ ) than the check variety BARI Gom-28 (3.72 tha ${ }^{-1}$ ) (Table 1).

Considering the Duration, yield \& yield attributes, the promising line BWM-M-1-1 will be evaluated for the next trial.

## Improvement of Binagom-1 through hybridization

To increase the heterosis for the yield and yield contributing traits, Binagom-1 and BARI Gom-33 were crossed. The $\mathrm{F}_{2}$ generation was cultivated under field settings utilizing after the $F_{1}$ seeds were harvested. In Rabi 2021-2022, $40 \mathrm{~F}_{2}$ genotypes were raised. At maturity, a single panicle from each genotype was collected. A similar approach was used in the previous Rabi season (2021-2022) to manage the $\mathrm{F}_{3}$ population.
To introgress short duration, heat tolerance, lodging resistance traits in Binagom-1 during November, 2020. The $\mathrm{BC}_{2} \mathrm{~F}_{1}$ seeds of Binagom- $1 \times$ BARI Gom- 32 from each plant of each cross were collected them to grow $\mathrm{BC}_{3} \mathrm{~F}_{1}$ population next year.

Considering the Duration, yield \& yield attributes, the promising lines will be evaluated for the next generation.

## Groundnut

## Regional yield trial with some $\mathbf{M}_{\mathbf{8}}$ mutants of groundnut

Groundnut (Arachis hypogaea L.) is mainly cultivated in more than 100 countries in the semi-arid and subtropic regions covering an area of 29.59 million hactare with 48.75 million tons production. The seeds and haulms are good sources of income as both cash and fodder crops. As a result, groundnut cultivation can provide sustainability to the mixed croplivestock production system which mostly prevails in semi-arid and subtropical regions especially in countries like Bangladesh. Mutation breeding can supplement conventional breeding by creating variability and enhancing the opportunity to improve the crop. Through mutation breeding, several high-yielding environmentally stable varieties of groundnut have already been developed in Argentina, India, Myanmar, and China. The key objective of the study was to figure out the adaptation of groundnut in Bangladesh by evaluating the effects of genotype, environment, and their interaction in respect of yield. Responsiveness and yield constancy of genotypes to 07 varying environments were also investigated using stability parameters.

Dry seeds of Binachinabadam-6 were irradiated at 282Gy of X-ray at the Agriculture and Biotechnology Laboratory of IAEA, Seibersdorf, Austria. Continuous evaluation and selection were made to advance the lines until $\mathrm{M}_{8}$. Five groundnut mutant genotypes (B6/282/80, B6/282/63, RG-KHA-19/1, B6/282/64, and Binachinabadam-4) were used for the evaluation in two different seasons (Rabi). The experiment was conducted in seven different locations (Rangpur, Lalmonirhat, Ishwardi, Pakshi, Khagrachari, Panchari, and

Mymensingh). Thus, locations and seasons combined produced 07 environments for the evaluation (Table 61).

Table 61: Location coordinates and cultivation information of the 07 study area

| Location and year | Season | Longitude | Latitude | Sowing Date | Harvesting Date |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\begin{aligned} & \text { Mymensingh,2021- } \\ & 22 \end{aligned}$ | Rabi | $24^{\circ} 83$ ' | $90^{\circ} 41^{\prime}$ | 31January, 2021 | 16 June, 2021 |
| Rangpur, 2021-22 | Rabi | $25^{0} 75$, | $89^{\circ} 24^{\prime}$ | 02February, $2021$ | 15 June, 2021 |
| Lalmonirhat, 2021- $22$ | Rabi | $25^{0} 91{ }^{\prime}$ | $89^{\circ} 45^{\prime}$ | 11February, 2021 | 17 June, 2021 |
| Ishwardi, 2021-22 | Rabi | $24^{0} 12 \cdot$ | $89^{0} 06^{\prime}$ | 23 January, 2021 | 05 June, 2021 |
| Pakshi, 2021-22 | Rabi | $24^{0} 00$ | $89^{0} 1$ | 25 January, 2021 | 10 June, 2021 |
| Khagrachari, 2021- $22$ | Rabi | $23{ }^{0} 10$, | $91^{0} 98$, | 27 January, 2021 | 13 June, 2021 |
| Panchari, 2021-22 | Rabi | $23^{0} 29$, | $91^{\circ} 89$, | 29 January, 2021 | 15 June, 2021 |

The experiment was conducted with RCB design with three replicates. A unit plot size was $3.0 \mathrm{~m} \times 1.0 \mathrm{~m}$. Seeds were sown at 15 cm distances within rows of 30 cm apart. Recommended fertilizer dose, cultural and intercultural operations were also followed. The average monthly maximum temperature was the mean value of the recorded monthly maximum temperatures during the study period, whereas the mean monthly minimum temperature was the mean value of the recorded monthly minimum temperatures (Figure12). No irrigation was used for the evaluation as the rainfall was sufficient enough for the groundnut cultivation.

Figure12. Monthly average weather data of the 07 environments during 2021-22
Data were recorded on plant height, pod number, pod yield plant ${ }^{-1}, 100$-pod and kernel weight from randomly selected 10 competitive plants at maturity. Pod yield was also
recorded from an area of $1.0 \mathrm{~m}^{2}$ which later converted to tha ${ }^{-1}$. Analysis was carried out using Statistix 10 version 1.0 Copyright @ 1985-2013.

Results showed significant variations among the mutants and check for most of the characters in individual locations and over locations in combined analysis (Table 62). On average, it was observed that plant height of B6/282/64, B6/282/80 and B6/282/63 was recorded which ranged from $67.60(\mathrm{~cm})$, $68.42(\mathrm{~cm})$ and $72.55(\mathrm{~cm})$. Another mutant RG-KHA-19-1 gave highest plant height $101.70(\mathrm{~cm})$ followed by the check variety Binachinabadam-4 68.39(cm). For pod plant ${ }^{-1}$ no significant differences were found with check variety but higher no. of pod observed (Table-5) and mutant RG-KHA-19-1 gave significantly lower than check for this trait. Pod \& kernel weight of the mutant B6/282/80 was 15.56 (g.) \& 11.03 (g.) which showed higher than the check variety Binachinabadam-4. 100 Pod-weights \& 100 Kernel-weight of the mutants were observed that B6/282/63, B6/282/64 and B6/282/80 were recorded from $78.45(\mathrm{~g}), 80.77(\mathrm{~g})$ and $79.21(\mathrm{~g}) \& 31.65(\mathrm{~g}), 32.71(\mathrm{~g})$ and $35.16(\mathrm{~g})$, other mutant RG-KHA-19-1 was recorded highest 100 Pod-weights \& 100 Kernel-weight 114.26(g.) \& 40.76(g) than the check variety Binachinabadam-4 ( 84.14 gm ). 100 kernel wt. also recorded higher in mutant RG-KHA-19-1 (47.08 gm) than the check variety Binachinabadam-4 was 78.04(g) \& $34.72(\mathrm{~g})$. From table 5 the shelling percentage of the mutant $\mathrm{B} 6 / 282 / 80$ was 70.74 significantly higher than the check variety Binachinabadam-4. Yield of the mutants of B6/282/80 was ( $2.71 \mathrm{kgha}^{-1}$ ) which was higher than the check variety Binachinabadam-4 ( $2.56 \mathrm{kgha}^{-1}$ ).

In a column, values with same letter (s) for individual location/ combined means do not differ significantly at $5 \%$ level $\mathrm{P} \geq 0.05$ and significant at $1 \%$ level $\mathrm{P} \geq 0.01$

The results supported from the Table 62 showed that different environment the shelling percentage of the mutant B6/282/80 was $70.74 \%$ significantly higher than the check variety Binachinabadam-4. Yield of the mutants of B6/282/80 was ( $2.71 \mathrm{kgha}^{-1}$ ) which was higher than the check variety Binachinabadam-4 $\left(2.56 \mathrm{kgha}^{-1}\right)$. Our study delineated that is a suitable genotype $\mathrm{B} 6 / 282 / 80$ that can be grown across the environment in Bangladesh while the other genotypes are environment-specific. Analysis suggests that an increase in yield can be
accomplished by dividing experimental regions as zonal trail and selected as a new variety for both season all the groundnut growing areas of Bangladesh.

## Screening $\mathrm{F}_{6-7}$ populations for long and bigger pods with 3-4 kernels

In Bangladesh groundnut is grown area of 15,500 acres with a production of 66,000 metric tons in Rabi and Kharif season (BBS, 2017) which is not sufficient for this country over 168 million people. Groundnut is ranked 4th among the oilseed crops in the world after soybean, rape seed and cotton. About $2 / 3$ of the world's total groundnut production is used to produce oil and the remaining $1 / 3$ is used in food products (Variath MT \& Janila P.2017). It is the third most important oil seed crop after mustard and sesame in Bangladesh (Miah MA \& Mondal MRI, 2017). Therefore, Groundnut seeds contain high quality edible oil (35-55 \%) that varies depending upon variety (Nelson et al., 1995), season and maturity (Hashim et al 1993), Groundnut oil is considered as stable and nutritive as it contains right proportions of saturated and unsaturated fatty acids. The key objective of the study was to figure out the adaptation of groundnut in Bangladesh by evaluating the effects of yield and yield contributing characters using stability parameters and identify 3-4 seeded higher shelling percentages, early maturing, high quality edible oil and high yielding mutant(s).

Using a $4 \times 4$ intra-specific diallel cross of groundnut. Breeding material comprised of a set of two mutant groundnut genotypes viz., GC (24)-1-1-1 and China Badam, having diverse origin. Five groundnut partial mutant genotypes (G3×G1-2, G3×G4-1, G3×G4-5, and G3 $\times$ G1-3 \& G4 $\times$ G2-2) with two parents were used for the evaluation in two different seasons (Kharif and Rabi). The experiment was conducted at the field experimental plot of Bangladesh Institute of Nuclear Agriculture (BINA), Mymensingh, Bangladesh during the period of July 2021 to June 2022.
Table 63. Location coordinates and cultivation information of the study area

| Location and year | Season | Longitude | Latitude | Sowing Date | Harvesting Date |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Mymensingh,2021-22 | Kharif | $24^{\circ} 83^{\prime}$ | $90^{\circ} 41^{\prime}$ | 03 August, 2021 | 05 January, 2022 |
| Mymensingh,2021-22 | Rabi | $25^{\circ} 75^{\prime}$ | $89^{\circ} 24$, | 02February, 2022 | 15 June, 2022 |

The experiment was conducted with RCB design with three replicates. A unit plot size was $3.0 \mathrm{~m} \times 3.0 \mathrm{~m}$. Seeds were sown at 15 cm distances within rows of 30 cm apart. Recommended fertilizer dose, cultural and intercultural operations were also followed. No irrigation was used for the evaluation as the rainfall was sufficient enough for the groundnut cultivation. Data were recorded on plant height, pod number, pod yield plant ${ }^{-1}, 100-\operatorname{pod}$ and kernel weight from randomly selected 10 competitive plants at maturity. Pod yield was also recorded from an area of $1.0 \mathrm{~m}^{2}$ which later converted to tha ${ }^{-1}$. Oil content was determined using Soxhlet method (Jambunathan et al., 1993) with minor modifications. Two gram of oven dried groundnut seeds of each genotype were weighed and pulverized into fine powder with amortar and pestle. Then the groundnut meal was extracted with petroleum benzene for 17 hrs in Soxhlet apparatus. Powder weight before and after extraction was taken, the difference between the two weights was expressed in terms of oil percentage. The advantage of using Soxhlet extraction is that the solvent used in this method penetrates faster to the kernel powder, dissolve oil in the solvent and make a complete extraction. Additionally, this method is very efficient, quick, requires less solvent and convenient for automation and is more acceptable than other extraction methods. Analysis was carried out using Statistix 10 version 1.0 Copyright @1985-2013.

Significant variation was showed among the cross combinations and the parents for most of the characters (Table 64). Highest plant height was observed from the cross G4. Pods Plants ${ }^{-1}$ were higher in G3×G4-5 (23.93) \& G3×G1-3 (23.73) than the two parent. For Pod weight \& kernel weight no significant differences were found with parents but higher no. of pod observed (Table-7) and partial mutant G3×G4-1 gave significantly lower than check for this trait. 100 pod weight \& 100 Kernel weight was recorded highest in G3×G1-3 (145.83 g.) \& $(67.07 \mathrm{~g})$ than the two parent. From table 7 the shelling percentage of the partial mutant G3 $\times$ G1-3 was $75.14 \%$ significantly higher than the check than the two parents. In oil content, the partial mutant line G3×G1-3 showed the highest percentage of oil content ( $52.30 \%$ ) where as parent G3 showed the lowest ( $45.1 \%$ ) content of oil (Table 63). Highest yield was recorded in the cross combination G3×G1-3 (3.27 tha ${ }^{-1}$ ) which was significantly higher than all two parents studied in the experiment.

It can be concluded that the selected advanced mutants of groundnut genotypes G3×G1-3, G4×G2-2 \& G3 $\times$ G4-5 are good in analysis which might be the excellent source of nutrition. Induced mutation through radiation could be the mentionable variations in the yield and functional properties of genotypes. Considering yield \& yield attributes of the partial mutant G3 $\times$ G1-3, G4 $\times$ G2-2 \& G3 $\times$ G4-5 is the best performer among all mutants used in this study. The findings presented in this comparative study of biochemical properties will be helpful for the further breeding program.

## Rapeseed-Mustard

## On-station and on-farm yield trial with advanced $\mathrm{F}_{8}$ rapeseed (B. rapa var toria) lines

Four $\mathrm{F}_{8}$ rapeseed lines (RL11, RL13, RL14 and RL17) along with two check varieties Tori-7 and Binasarisha-10 were evaluated to assess overall performance for earliness and yield attributes. The trial was conducted at BINA Head Quarter farm, Mymensingh and BINA substation farms at Ishurdi, Nalitabari, Rangpur, Magura \& Jamalpur. The same experiment was conducted at the farmers' field at Rangpur, Manikgonj and Tangail. The experiment was laid out in a randomized complete block design with three replications. Seeds were sown on 15 November 2021 at all the location. Unit plot size was $16 \mathrm{~m}^{2}(4 \mathrm{~m} \times 4 \mathrm{~m})$ and line to line distance was 25 cm . Recommended production packages i.e., application of fertilizers, weeding, thinning, etc. were followed to ensure normal plant growth and development. Data on plant height, branches plant ${ }^{-1}$, siliquae plant ${ }^{-1}$, siliqua length and seeds siliqua ${ }^{-1}$ was taken from 10 randomly selected plants from each plot. Maturity period was counted when $90 \%$ siliquae were matured in a plot. Seed yield of each plot was recorded after harvest with proper drying and then converted into $\mathrm{kg} \mathrm{ha}{ }^{-1}$. Appropriate statistical analyses were performed for comparison of mean of each character.

Results obtained from the trial of individual location and combined mean over location for all the characters are presented in the Table 66. Significant variation was observed among the lines and check varieties for most of the characters in each location and combined over all location. Average, maturity period ranged from 80 to 83 days. RL-14 and RL-17 required longest maturity period of 83 days and Tori-7 required the 81 days, whereas Binasarisha-10 required 80 days. In case of plant height, RL-14 produced the tallest plant $(110 \mathrm{~cm})$ followed by RL-13 ( 101 cm ) and Binasarisha- $10(100 \mathrm{~cm})$. RL-13 produced the highest number of branches plant ${ }^{-1}$ (5) among other genotypes. RL-17 produced the highest number of siliquae plant ${ }^{-1}$ (159) followed by RL-11 (151). The number of seeds siliquae ${ }^{-1}$ and siliquae length is a
good indicator for contributing seed yield. Seeds siliquae ${ }^{-1}$ and siliquae length of all the genotype significantly differ from each other. The longest siliquae was found in RL-13 $(6.3 \mathrm{~cm})$ whereas, the shortest $(4.5 \mathrm{~cm})$ was in Tori- 7 .

N. B.: In a column, values with same letter(s) for individual location/combined mean do not differ significantly at 5\% level. BINA-10 means Binasarisha-10.

Among the genotypes, line RL-17 produced highest seed yield $1561.4 \mathrm{~kg} \mathrm{ha}^{-1}$ followed by RL-11 ( $1521.2 \mathrm{~kg} \mathrm{ha}^{-1}$ ) which was statistically different from seed yield of check variety Binasarisha-10 ( $1226.3 \mathrm{~kg} \mathrm{ha}^{-1}$ ) and Tori-7 ( $1243.9 \mathrm{~kg} \mathrm{ha}^{-1}$ ). Higher seed yielded lines RL-17 and RL-11 have been selected for future trial. Location-wise performance was higher at BINA Sub-station Rangpur ( $2046.3 \mathrm{~kg} \mathrm{ha}{ }^{-1}$ ) followed by BINA Sub-station Nalitabari ( $1883.3 \mathrm{~kg} \mathrm{ha}^{-1}$ ) and lowest in BINA Sub-station, Magura ( $1234.4 \mathrm{~kg} \mathrm{ha}^{-1}$ ). From the above results it can be concluded that RL-17 and RL-11 have been selected for future trial on the basis of their yield stability and other agronomic traits.

## Regional yield trial with $\mathbf{M}_{8}$ rapeseed (B. napus) mutant

Three rapeseed mutants (RM22, RM24 and RM26) along with mother variety Binasarisha-9 and check variety Binasarisha-4 was observed in this trial. The trial was conducted at BINA Head Quarter farm, Mymeningh and BINA sub-station farms at Nalitabari, Rangpur, Satkhira and Jamalpur. This experiment was laid out in a randomized complete block design with three replications. Seeds were sown on 17 November 2021. Unit plot size was $16 \mathrm{~m}^{2}(4 \mathrm{~m} \times$ 4 m ) and line to line spacing was 25 cm . Recommended production packages i.e., application of fertilizers, weeding, thinning, etc. were followed to ensure normal plant growth and development. Data on plant height, branches plant ${ }^{-1}$, siliquae plant ${ }^{-1}$ and seeds siliqua ${ }^{-1}$ were taken from 10 randomly selected plants from each plot. Maturity period was recorded when $90 \%$ siliquae were matured in a plot. Seed yield of each plot was converted into $\mathrm{kg} \mathrm{ha}^{-1}$. Appropriate statistical analyses were performed for comparison of mean of each character.

Results obtained from the trial of individual location and combined over location for all the characters are presented in the Table 67. Significant variation was observed among the lines and check varieties for most of the characters in both of individual location and combined over location. Average maturity period ranged from 83 to 90 days. All the mutants matured earlier than the mother variety Binasarisha- 9 and check variety Binasarisha-4. Check variety Binasarisha-4 produced the tallest plant ( 107.66 cm ) followed by RM-22 and RM-26 $(101.97 \mathrm{~cm}$ and 102.38 cm$)$ which had statistically similar plant height comparing with Binasarisha-9. Among the mutants, RM-24 was comparatively dwarf having 96.26 cm height and produced the equal number of branches plant ${ }^{-1}$. Among the mutants and checks Binasarisha-4 produced the highest number of siliquae plant ${ }^{-1}$ (138) followed by Binasarisha9 (133) and RM-26 (121).
Table 67. Mean performance of mutants and checks for different characters

N. B.: In a column, values with same letter(s) for individual location/combined mean do not differ significantly at 5\% level. BINA-4 \& BINA-9 means Binasarisha-4 \& Binasarisha-9.

Seeds Siliqua ${ }^{-1}$ and siliquae lengths were also contributing indicator for higher seed yield of rapeseed. Both of these characters are showed significant variation of all the genotypes. Binasarisha-4 produced the highest seed yield ( $1595.9 \mathrm{~kg} \mathrm{ha}^{-1}$ ) which was significantly different compared to the mutants and Binasarisha- 9 ( $1561.3 \mathrm{~kg} \mathrm{ha}^{-1}$ ). At BINA sub-station Rangpur, RM-26 produce maximum seed yield of $1658.0 \mathrm{~kg} \mathrm{ha}^{-1}$ and that was higher than any other tested genotypes. Considering with growth duration and agronomic performances and yield at stress prone area RM-26 was selected as a promising mutants for further stress breeding program of rapeseed.

## Preliminary yield trial with $\mathbf{M}_{6}$ rapeseed (B.rapa var. toria) mutants

Seven rapeseed mutants (RT-31, RT-32, RT-35, RT-38, RT-39, RT-42 and RT-77) along with the check variety Tori-7 was taken in the present investigation. This trial was conducted at BINA HQ farm, Mymensingh and BINA sub-station farms at Nalitabari, Noakhali, Satkhira and Jamalpur. The experiment was laid out in a randomized complete block design with three replications. Seeds were sown on $27^{\text {th }}$ November 2021 at both locations. Unit plot size was $20 \mathrm{~m}^{2}(5 \mathrm{~m} \times 4 \mathrm{~m})$ and line to line distance was 25 cm . Recommended production packages i.e., application of fertilizers, irrigation and pesticide, weeding, thinning, etc. were followed to ensure normal plant growth and development. Data on plant height, branches plant ${ }^{-1}$, siliquae plant ${ }^{-1}$, siliqua length and seeds siliqua ${ }^{-1}$ was taken from 10 randomly selected plants from each plot. Maturity period was counted when $90 \%$ siliquae were matured in a plot. Seed yield of each plot was recorded after harvest and proper drying and then
converted into $\mathrm{kg} \mathrm{ha}^{-1}$. Appropriate statistical analyses were performed for comparison of mean of each character.
Results obtained from the trial of individual location and combined over location for all the characters are presented in Table 68. Significant variation was observed among the lines and check variety for most of the characters in both of six individual locations and combined over all locations. On an average, maturity period ranged from 79 to 84 days. Mutant RT-35 required longest maturity period of 84 days and Tori- 7 required the shortest maturity period of 79 days. RT-35 $(101.67 \mathrm{~cm})$ and RT- $77(101.71 \mathrm{~cm})$ produced the tallest plant followed by RT-32 $(98.58 \mathrm{~cm})$. Mutant RT-39 ( 87.6 cm ) was comparatively dwarfed plant. The mutants RT-31, RT-35 and check RT-38 produced the similar number of branches (5) which is higher than the all other genotypes and check variety. RT-35 produced the highest number of siliquae plant ${ }^{-1}$ (135) followed by RT-42 and RT-39 which produced 127 \& 122 siliquae plant ${ }^{-1}$, respectively. Number of seeds siliquae ${ }^{-1}$ and siliquae length is good indicator contributing seed yields.

N.B.: In a column, values with same letter(s) for individual location/combined mean do not differ significantly at 5\% level.

Maximum Seeds Siliquae ${ }^{-1}$ and siliquae length was obtained from RT-38 (18 \& 4.88) and RT32 (15 \& 5.17) that was significantly differ from other mutants and check. Among the genotypes, line RT-35 produced higher seed yield of $1582.6 \mathrm{~kg} \mathrm{ha}^{-1}$ which was statistically similar to seed yield of RT-32 and RT-38 ( $1533.4 \mathrm{~kg} \mathrm{ha}^{-1} \& 1509.8 \mathrm{~kg}$ ha- ${ }^{-1}$ ). Location-wise performance was lowest at BINA sub-station Noakhali ( $1132.7 \mathrm{~kg} \mathrm{ha}{ }^{-1}$ ) and the highest was at BINA sub-station Nalitabari ( $1579.2 \mathrm{~kg} \mathrm{ha}^{-1}$ ). But individual performance at southern area was higher for RT-38 and RT-39 indicates that these mutants have stress tolerant potentiality. From the above said results it can be concluded that four mutants (RT-32, RT-35, RT-38 and RT-39) have been selected for future trial.

## Screening of rapeseed mutants for salinity tolerance in hydroponic culture

The objective of this experiment is to response of selected rapeseed genotypes in salt stress. Screening of salinity from a vast number of collected genotypes under field condition is quite difficult. It is also difficult to maintain accurate salinity levels in soil media in different treatments. In hydroponic culture solutions, it is easy to maintain the accuracy of salinity in respective treatments. Thus, this study was aimed to find out the salt tolerant genotypes using hydroponic screening techniques. Uniform seeds of RL-13, RL-14, RL-17 and Tori-7 was used in the present investigation. Salinity treatment in Figure 13 ( 8,10 and $12 \mathrm{dS} / \mathrm{m}$ ) was applied after every seven days when the entire seedling is established in hydroponic culture. Data on various characters such as plant height, leaf number, leaf area, shoot and root dry weight was taken from five randomly selected plants of each tray at reproductive stage.
Maximum, minimum and mean values of different plant characters of four rapeseed genotypes grown under different levels of saline condition are presented in Table 69 and visual injury at reproductive stage presented in table 5 . All the characters were sharply decreased due to salt injury. The plant height ranged from 35.3 to 52.9 cm with a mean of 45.1 cm in the control plants. However, at $8 \mathrm{dS} / \mathrm{m}$ salinity, the plant height ranged from 26.63 to 41.6 cm with a mean of 32.8 cm . Number of leaves per plant ranged from 14.3 to 19.1 with a mean of 15.71 in the control plants. At $8 \mathrm{dS} / \mathrm{m}$ salinity, that was reduced and found from 9.0 to 22.0 with a mean of 15.33 ; and 31.3-48.2 with a mean of 29.4 for leaf area $\left(\mathrm{cm}^{2}\right.$ plant ${ }^{-}$ ${ }^{1}$ ). Like other traits root and shoot dry weight also decreased due to salinity effect. Among the different plant characters' leaf number as well as leaf area was more sensitive to salinity than others. RL-13 and RL-14 were found moderately salt tolerant than other genotypes and these two genotypes can be used as a breeding material for developing salt tolerant varieties in near future.

Table 69. Range and mean values of different quantitative characters of four rapeseed genotypes grown at $8 \mathrm{dS} / \mathrm{m}$ salinity level

| Plant Characters | Control |  | $8 \mathrm{dS} / \mathrm{m}$ |  |

## Growing of $\mathbf{M}_{6}$ to $\mathbf{M}_{2}$ generation of rapeseed mutants

A large number of $\mathrm{M}_{6}, \mathrm{M}_{5}, \mathrm{M}_{4}, \mathrm{M}_{3}$ and $\mathrm{M}_{2}$ variants was developed from different irradiated materials were grown for selecting desirable mutant at BINA Head Quarter farm, Mymensingh. The seeds were sown on $20-26^{\text {th }}$ November 2021. All the seeds were space planted in 3 m long five rows with 30 cm row spacing. Recommended fertilizer was applied and necessary steps were taken to grow the crop uniformly.
Total 146 segregating population (Table 71) was evaluated for yield and yield contributing characters. Among these, 40 segregating families $\left(M_{6} \& M_{5}\right)$ and others was (106) single plant. All of these segregating populations were obtained from earlier generation, that have been selected from previous trials, whereas, single plant population was from earlier generation of $\mathrm{M}_{4}, \mathrm{M}_{3}$ and $\mathrm{M}_{2}$. Total eight populations from $\mathrm{M}_{6}$ and 14 from $\mathrm{M}_{5}$ was selected for future advancement of generation. The basis of the selection was considering the maturity period (78-83 days) with other yield contributing characters. From various early generation single plant also selected considering maturity period, seed color, no. of silique and other agronomic traits. Fifty-eight single plants also selected and harvested separately for future utilization of varietal improvement program. From all of these variants a total of 80 true breeding mutants have been selected primarily for further selection that will be grown for respective advance generation on the basis of their agronomic performances.

Table 71: Selected plants \& families of $\mathbf{M}_{6}, M_{5}, M_{4}, M_{3}$ and $\mathbf{M}_{2}$ population

| Segregating <br> population | No. of families <br> planted | No. of families <br> selected | No. of single plant <br> selected |
| :---: | :---: | :---: | :---: |
| $\mathrm{M}_{6}$ | 22 | 8 | - |
| $\mathrm{M}_{5}$ | 28 | 14 | - |
| $\mathrm{M}_{4}$ | 17 | - | 09 |
| $\mathrm{M}_{3}$ | 32 | - | 17 |
| $\mathrm{M}_{2}$ | 47 | - | 32 |
| Total | 146 | 22 | 58 |

## Growing of $F_{5}$ to $F_{2}$ population of rapeseed generation

The objective of this research was to select desirable population on the basis of phenotypic performance for advancing the generation. A large number of $\mathrm{F}_{5}, \mathrm{~F}_{4}, \mathrm{~F}_{3}$ and $\mathrm{F}_{2}$ variants were developed from various cross between Binasarisha- $9 \times$ BARI Sarisha-14, Binasarisha- $9 \times$ Tori7, Binasarisha- $9 \times$ BARI Sarisha-18, Tori-7×BARI Sarisha-18 were grown at BINA Head Quarter farm, Mymensingh. The seeds were sown on $26-30^{\text {th }}$ November 2021. All the seeds
were planted in 3 m long five rows with 30 cm row spacing. Recommended fertilizer was applied and necessary actions were taken to grow the crop uniformly.
Total 83 segregating population was evaluated for yield and yield contributing characters. Among them 26 was segregating families and other 57 was single plant. All of the segregating populations were obtained from earlier generation that have been selected from previous trials, whereas single plant population was from earlier generation of $F_{4}$ to $F_{2}$. Five populations from $\mathrm{F}_{5}$ and 11 from $\mathrm{F}_{4}$ was selected for future generation advancement. The selection was facilitated considered the early maturity period (78-80 days) with other yield contributing characters. From various early generation single plant also selected considering maturity period, seed color, no. of siliqua and other agronomic traits. Thirty-four single plants have been selected and harvested separately for future utilization of varietal improvement program. A total of 50 true breeding lines have been selected primarily for further selection that will be grown respective advance generation on the basis of their agronomic performances.

Table 72: Selected plant \& families of $\mathrm{F}_{5}, \mathrm{~F}_{4}, \mathrm{~F}_{\mathbf{3}}$ and $\mathrm{F}_{\mathbf{2}}$ populations

| Segregating <br> population | No. of families <br> planted | No. of families <br> selected | No. of single plant <br> selected |
| :---: | :---: | :---: | :---: |
| $\mathrm{F}_{5}$ | 9 | 5 | - |
| $\mathrm{F}_{4}$ | 17 | 11 | - |
| $\mathrm{F}_{3}$ | 42 | - | 27 |
| $\mathrm{~F}_{2}$ | 15 | - | 7 |
| Total | 83 | 16 | 34 |

## Growing of $M_{1}$ generation of rapeseed

The well dried seed of BARI Sarisha-18, Binasarisha-11, Binasarisha-9 and Tori-7 was used for the advancement of new generation. Thirty seeds were exposed to four doses of gamma rays (500, 600, 700, and 800 Gy ). Prior to mutagenic treatment, seeds were kept in desiccators for moisture equilibration. The seeds were irradiated by gamma rays $\left({ }^{60} \mathrm{Co}\right.$ irradiator) at BINA Mymensingh. The response variables, percent germination and survival rate was counting after 21 days of sowing.
The highest percentages seed germination occurred with the doses of 500 and 600 Gy , whose values were $88-90 \%$ and $72-80 \%$ respectively decrease progressively as the radiation dose was increased (Figure 14). Survival rate was a consequence of germination percentage. As the radiation dose increased from 700 to 800 Gy , the percentage of survival decreased, indicating that the like others rapeseeds also a sensitive species at high levels of radiation (Figure 13). Survived plants that able to produced seeds were harvested separately for growing $\mathrm{M}_{2}$ generation.

Fig 14: Germination (left) and survival percentage (right) of rapeseed seedlings subjected to four levels of ${ }^{60} \mathrm{Co}$ gamma radiation

## Hybridization of Binasarisha-9 and Tori-7 with BARI Sarisha-14, BARI Sarisha-17 \& BARI Sarisha-18

The aim of this study is to create genetic variability for varietal development process of rapeseeds. Binasarisha-9 and Toria-7 was crossed with BARI Sarisha-14, BARI Sarisha-17 and BARI Sarisha-18. The seeds were sown on 10 days' interval from $30^{\text {th }}$ November 2021. In early morning the recipient parent was emasculated and pollinated by the respective donor parents followed by bagging and tagging. After 3-5 days the bag was removed and seed setting siliqua was consider as a success of cross.
Maximum cross was conducted between Binasarisha- $9 \times$ BARI Sarisha- 18 followed by Binasarisha- $9 \times$ BARI Sarisha- 14 and success rate was higher in Binasarisha- $9 \times$ BARI Sarisha$1856 \%$, followed by Binasarisha- $9 \times$ Tori- $7,53 \% . \mathrm{F}_{1}$ seeds were harvest separately for growing $\mathrm{F}_{2}$ population.

Table 72: Crossing detail with success percentage

| Cross combination | No of flowers <br> pollinated | No. of <br> success | Percent of <br> success |
| :--- | :---: | :---: | :---: |
| Binasarisha- $9 \times$ BARI Sarisha-14 | 25 | 12 | 48 |
| Binasarisha-9 $\times$ Tori-7 | 15 | 08 | 53 |
| Binasarisha-9 $\times$ BARI Sarisha-18 | 30 | 17 | 56 |
| Tori-7 $\times$ BARI Sarisha-18 | 30 | 11 | 36 |

## Sesame

## On-station and on-farm yield trial with promising $M_{6}$ sesame mutants in Kharif-I

Two promising mutants along with one check variety Binatil-1 were evaluated through this trial. This experiment was conducted at BINA sub-station farms at Ishurdi, Magura \& farmer's field Mymensingh during March to June 2022. The mutants and the check variety were laid out in a randomized complete block design with three replications. Unit plot size was $20 \mathrm{~m}^{2}(4 \mathrm{~m} \times 5 \mathrm{~m})$ and line to line spacing was maintained 25 cm . Seeds were sown on March 2022. Recommended production packages like application of recommended doses of fertilizers, irrigation, weeding, thinning, etc. were followed to ensure normal plant growth and development. Data were taken on plant height, number of branches plant ${ }^{-1}$, number of capsules plant ${ }^{-1}$ and number of seeds capsule ${ }^{-1}$ from 10 randomly selected plants of each plot. Maturity period was counted when $80 \%$ capsules were matured and most of the plants turned into straw or yellowish color in each plot. Seed yield of each plot was converted into $\mathrm{kg} \mathrm{ha}^{-1}$. Appropriate statistical analyses were performed for comparison of mean of each character. Results obtained from the trial of individual location and combined over locations for all the characters are presented in Table 74. Significant variations were found among the mutants and the check variety for most of the characters in both of individual locations and combined over locations. No-significant variation was observed for days to maturity, branches plant ${ }^{-1}$ (no.) and capsule length (cm). On an average, days to maturity ranged from 86 to 87 days. The check variety Binatil- 1 produced the tallest $(102 \mathrm{~cm}$ ) plant followed by the mutant SM$026(90 \mathrm{~cm})$ and mutant SM-025 produced the shortest plant height of 83 cm . The mutant SM026 bear 2 branches but the mutant SM-025 and the check variety Binatil-1 were uniculm type. Mutant SM-026 produced significantly higher number of capsules plant ${ }^{-1}$ (57) followed by Binatil-1 (48) and the mutant SM-025 produced only 46 number of capsules plant ${ }^{-1}$. The mutant SM-026 had the highest number of seeds capsaules ${ }^{-1}$ (71) with long capsule ( 3.9 cm ) size, which is statistically identical from others. The mutant SM-025 had 56 number of seeds capsaules ${ }^{-1}$ with 2.72 cm long where as Binalit-1 had 64 number of seeds capsaules ${ }^{-1}$ with 3.7 cm capsule length. On an average, SM-026 produced the highest seed yield of 1293 kg ha${ }^{1}$ followed by the check variety Binatil- $1\left(1159 \mathrm{~kg} \mathrm{ha}^{-1}\right)$ and the mutant SM-025 produced lowest seed yield of $1074 \mathrm{~kg} \mathrm{ha}^{-1}$. Location-wise performance showed that the highest seed yield was produced at farmer's field Mymensingh ( $1232 \mathrm{~kg} \mathrm{ha}^{-1}$ ).

N. B.: In a column, values with same letter(s) for individual location/combined means do not differ significantly at $5 \%$ level.

From this trial it was observed that, SM-026 was the best mutant among the mutants and check. This mutant will be applied to the NSB for releasing as a new variety.

## Preliminary yield trial with promising $M_{5}$ sesame mutants at Kharif-I

Six promising mutants along with two check varieties Binatil-4 \& BARI Til-4 were evaluated through this trial. This experiment was conducted at BINA HQ farm Mymensingh and BINA sub-station's farm at Ishurdi during March to June 2022. The mutants and the check varieties were laid out in a randomized complete block design with three replications. Unit plot size was $20 \mathrm{~m}^{2}(4 \mathrm{~m} \times 5 \mathrm{~m})$ and line to line spacing was maintained 25 cm . Seeds were sown on March 2022. Recommended production packages like application of recommended doses of fertilizers, irrigation, weeding, thinning, etc. were followed to ensure normal plant growth and development. Data were taken on plant height, number of branches plant ${ }^{-1}$, number of capsules plant ${ }^{-1}$ and number seeds capsule ${ }^{-1}$ from 10 randomly selected plants from each plot. Maturity period was counted when $80 \%$ capsules were matured and most of the plants turned into straw or yellowish color in each plot. Seed yield of each plot was converted into $\mathrm{kg} \mathrm{ha}^{-1}$. Appropriate statistical analyses were performed for comparison of means of each character.
Results obtained from the trial of individual location and combined over locations for all the characters are presented in Table 75. Significant variations were observed among the mutants and two checks for most of the characters in both of individual locations and combined over locations. On an average, days to maturity ranged from 78 to 97 days. Mutants ESE-01, ESE-

04 and check variety BARI Til-04 produced the tallest plant (127cm) whereas mutant ESE-06 produced the shortest plant height $(114 \mathrm{~cm})$. Both the mutants and checks were profusely branched and BARI Til-04 provided maximum (4) branches plant ${ }^{-1}$ followed by the mutant ESE-02 (3). Mutant ESE-03 produced significantly higher number of capsules plant ${ }^{-1}$ (61) which is statistically different from others. Lowest number of capsules plant ${ }^{-1}$ (49) was obtained from ESE-05. Mutant ESE-03 produced highest number of seeds capsaule ${ }^{-1}$ (80) followed by the mutant ESE-01 (73). Mutant ESE-01 had long capsule length ( 2.65 cm ) and highest thousand seed weight $(3.36 \mathrm{~g})$ which is statistically identical from others. On an average, Mutants ESE-01 and ESE-03 produced the highest seed yield of ( $1515 \mathrm{~kg} \mathrm{ha}{ }^{-1}$ ) and ( $1509 \mathrm{~kg} \mathrm{ha}^{-1}$ ), respectively followed by mutant's ESE-06 (1468kg ha ${ }^{-1}$ ) and ESE-04 (1406 $\mathrm{kg} \mathrm{ha}{ }^{-1}$ ). Location-wise performance showed that the highest seed yield was produced at BINA HQ farm, Mymensingh ( $1391 \mathrm{~kg} \mathrm{ha}^{-1}$ ).

[^0]From this result, it was concluded that mutant's ESE-01 and ESE-03 performed better in yield and other yield contributing characters. Further trials will be needed to confirm this result.

## Growing of $\mathrm{M}_{\mathbf{5}}$ population

A large number of $\mathrm{M}_{5}$ populations from local landrace Pahari Til were grown in plant progeny rows at BINA HQ farm, Mymensingh. The purpose of this study was to select the true breeding mutants having higher seed yield and early maturity. Recommended production packages like as application of recommended doses of fertilizers, irrigation and pesticide, weeding, thinning, etc. were followed to ensure normal plant growth and development. Data was considered for plant height, number of branches plant ${ }^{-1}$, number of capsules plant ${ }^{-1}$ and number seeds capsule ${ }^{-1}$. From these data, a total of 5 mutants have been selected based on early maturity and higher seed yield potentiality. All of those mutants need further evaluation in subsequent generations.

## Growing of $\mathbf{M}_{\mathbf{4}}$ population

A large number of $\mathrm{M}_{4}$ populations from Binatil-2 (from three different doses) were grown in plant progeny rows at BINA HQ farm, Mymensingh. The purpose of this study was to select the true breeding mutants having higher seed yield and early maturity. Recommended production packages like as application of recommended doses of fertilizers, irrigation and pesticide, weeding, thinning, etc. were followed to ensure normal plant growth and development. Data was considered for plant height, number of branches plant ${ }^{-1}$, number of capsules plant ${ }^{-1}$ and number seeds capsule ${ }^{-1}$. From these, a total of 10 mutants have been selected based on early maturity and higher seed yield potentiality. All these mutants need further evaluation in subsequent generations.

## Growing of $\mathbf{M}_{\mathbf{3}}$ population

A large number of $\mathrm{M}_{3}$ population from two popular sesame varieties Binatil-2 and Binatil-4 (from four different doses) were grown in plant progeny rows for selecting desirable mutants at BINA HQ farm, Mymensingh. The objective of this study was selecting true breeding desirable mutants having higher seed yield, single husk and early maturity. Recommended production packages like application of recommended doses of fertilizers, irrigation, weeding, thinning, etc. were followed to ensure normal plant growth and development. Data was considered for plant height, number of branches plant ${ }^{-1}$, number of capsules plant ${ }^{-1}$ and number seeds capsule ${ }^{-1}$. From them primarily, a total of 16 mutants have been selected based on early maturity and higher seed yield potentiality. All of these mutants need further evaluation in subsequent generations.

## Growing of $\mathbf{M}_{\mathbf{2}}$ population

To create genetic variability, seeds of popular sesame varieties Binatil-2 were irradiated earlier with $600,700,800$ and 900Gy of gamma rays. Seeds were sown on 27 March 2021 at BINA HQ farm, Mymensingh. This experiment was followed by non-replicated design and sown separately (variety and dose wise). Finally, the survived plants that produced seeds were harvested separately for growing $\mathrm{M}_{3}$ population.

## Soybean

## On-station and on-farm yield trial with selected $M_{7}$ soybean mutants

Three promising mutants (SBM-12, SBM-15 and SBM-17) along with two checks Binasoybean-2 and Binasoybean-6 were evaluated through this trial. The experiment was conducted at BINA HQ farm Mymensingh, BINA sub-station farms at Magura, Rangpur, Satkhira and farmers' field at Noakhali, Laxmipur, Chandpur and Barishal during January to April 2022. This experiment was laid out in a randomized complete block design with three replications. Sowing was done within first week of January. Spacing between rows was 30 cm and $5-8 \mathrm{~cm}$ between plants in a row. Unit plot size was $12 \mathrm{~m}^{2}(4 \mathrm{~m} \times 3 \mathrm{~m})$. Recommended management practices were followed to ensure proper growth and development of plants. Data on various characters such as plant height, number of branches plant ${ }^{-1}$, pods plant ${ }^{-1}$ and seeds pod $^{-1}$ were taken from 10 randomly selected plants of each plot. Maturity period was counted when the plant and pods of each plot turned into yellowish brown color and almost all the leaves spill. Seed yield of each plot was recorded and converted into $\mathrm{kg} \mathrm{ha}{ }^{-1}$. Data recorded from the experiment was analyzed following appropriate statistical analysis.
Results obtained from this trial of individual location and combined over locations for all the characters are presented in Table 76. Significant variations were observed among the mutants and check varieties for most of the characters in both of individual locations and combined over locations. On an average, maturity period ranged from 108 to 113 days and there were no statistical differences among the mutants and check varieties. Binasoybean-2 earlier than other and it requires 108 days to mature where Binasoybean- 6 requires highest 113 days to mature. Similar days to maturity 111 days were obtained from SBM-12, SBM-15 and SBM17. Plant height ranged from 34 cm in Binasoybean -2 to 59 cm in Binasoybean- 6 . There were no significant differences for Branches plant ${ }^{-1}$ among the mutants and check varieties. The mutants SBM-12 and SBM-15 produced the highest number of pods plant ${ }^{-1}$ (46) and seeds pod $^{-1}$ (3). Two check varieties Binasoybean-2 and Binasoybean-6 produced 43 and 41 pods plant ${ }^{-1}$, respectively. Pod length ranged from 4.0 cm (Binasoybean-6) to 3.0 cm (SBM-17 and Binasoybean-2). The highest hundred seed weight was found from the mutants SBM-15 $(12.5 \mathrm{~g})$ and SBM-17 (12.6g). Mutant SBM-12 produced the highest seed yield of 2592 kg ha ${ }^{1}$ followed by Binasoybean-2 ( $2457 \mathrm{~kg} \mathrm{ha}^{-1}$ ) and SBM-15 ( $2215 \mathrm{~kg} \mathrm{ha}{ }^{-1}$ ). Among the locations the highest seed yield of $2650 \mathrm{~kg} \mathrm{ha}^{-1}$ was obtained from BINA HQ Mymensingh followed by BINA sub-station farm Rangpur ( $2608 \mathrm{~kg} \mathrm{ha}^{-1}$ ).

N. B.: In a column, values with same letter(s) for individual location/combined means do not differ significantly at $5 \%$ level. BINA-2 means

Binasoybean-2 \& BINA-6 means Binasoybean-6
From this trial, it was observed that SBM-12 and SBM-15 was the best performer among the mutants. Mutant SBM-12 has been released as a new mutant variety named as BINA soybean 7.

## Regional yield trial with selected $\mathbf{M}_{6}$ soybean mutants

Three promising mutants (SMB-22, SMB-23 and SMB-25) along with two check varieties Binasoybean-2 and Binasoybean-6 were evaluated through this trial. This experiment was conducted at BINA sub-station farms at Noakhali, Barishal, Satkhira, Magura and Rangpur during January to April 2022. This experiment was laid out in randomized complete block design with three replications. Sowing was done on 14 January 2022. Spacing between rows was 30 cm and $7-10 \mathrm{~cm}$ between plants in a row. Unit plot size was $12 \mathrm{~m}^{2}(4 \mathrm{~m} \times 3 \mathrm{~m})$. Recommended management practices were followed to ensure proper growth and development of plants. Data on various characters such as plant height, number of branches plant ${ }^{-1}$, pods plant ${ }^{-1}$ and seeds pod ${ }^{-1}$ were taken from 10 randomly selected plants of each plot. Maturity period was counted when the plant and pods of each plot turned into yellowish brown color and almost all the leaves shed. Seed yield of each plot was recorded and converted into $\mathrm{kg} \mathrm{ha}^{-1}$. Data recorded from the experiment were analyzed following appropriate statistical design.
On an average, maturity period ranged from 109 days (Binasoybean-2) to 114 days (SBM23). Plant height ranged from 34 cm (Binasoybean-2) to $62 \mathrm{~cm}(\mathrm{SBM}-23)$ and branches plant ${ }^{-1}$ ranged from 2.9 (Binasoybean-2) to 3.6 (SBM-22). Mutant SBM-22 produced highest pods plant ${ }^{-1}$ (77); whereas, the check varieties Binasoybean-2 and Binasoybean-6 produced 43 and 53 pods plant-1, respectively. Binasoybean-6, SBM-22 and SBM-23 produced the highest number of seeds pod $^{-1}$ (4). Mutant SBM-25 had the highest pod length (2.88) followed by Binasoybean-2 (2.70) and mutants SBM-23 (2.67). Hundred seed weight was higher in Binasoybean-2 (13.34g) and lower hundred seed weight was obtained from SBM-23 (11.1g).

Seed yield obtain from the mutants and checks were significantly differ from each other's. Mutant SBM-25 produced the highest seed yield of $2836 \mathrm{~kg} \mathrm{ha}^{-1}$ followed by SBM-22 (2696 $\mathrm{kg} \mathrm{ha}{ }^{-1}$ ). Among the locations the highest seed yield was obtained from BINA sub-station farm Satkhira ( $2758 \mathrm{~kg} \mathrm{ha}^{-1}$ ) followed by the BINA sub-station farm at Barishal ( 2714 kg ha${ }^{1}$ ).

N.B.: In a column, values with same letter do not differ significantly at $5 \%$ level. BINA-2 means Binasoybean-2 \& BINA-6 means

Binasoybean-6
From this experiment, it was observed that SBM-25 was the best performer among the mutants and checks (Table 12). Further trials will be needed to confirm the result.

## Evaluation of promising salt tolerant soybean genotypes in pot culture

Three promising soybean mutants SBM-22, SBM-25 and SBM-26 along with three soybean varieties Binasoybean-2 (Parent), Binasoybean-6 and Lokon were evaluated to investigate the performance in saline condition. The experiment was conducted at BINA HQ, Mymensingh during Jan to April 2022, and laid out in a completely randomized design (CRD) with three replications. Before seed sowing, artificial salinity was created with NaCl and maintained 4 $\mathrm{dS} / \mathrm{m}, 6 \mathrm{dS} / \mathrm{m}$ and $8 \mathrm{dS} / \mathrm{m}$ in each pot ( 10 kg soil in each pot). Data on various characters such as plant height, number of leaves plant ${ }^{-1}$, leaf area and chlorophyll content (SPAD meter) was recorded from five randomly selected plants of each doses.
Comparing with imposed salinity level and time, plant height as well as leaf was decreased. All the germinated genotypes were survived at $4 \mathrm{dS} / \mathrm{m}$ up to 21 days (Table 78). All the mutants showed moderately tolerant at $4 \mathrm{dS} / \mathrm{m}$ up to 7 days after sowing. Furthermore, Binasoybean-2, Binasoybean-6 and Lokon performed well with the advancement of time.

Table 78. Visual salt injury at seedling stage

| Binasoybean-6 | HT | NG | NG | HT | NG | NG | MT | NG | NG |
| Lokon | HT | NG | NG | HT | NG | NG | HT | NG | NG |

N.B.: HT= Highly tolerant, $\mathrm{T}=$ Tolerant, MT= Moderately tolerant, $\mathrm{S}=$ Susceptible, HS= highly susceptible and $\mathrm{NG}=$ Not germinated.

Fig. 15: Chlorophyll content of selected genotypes at saline and non-saline condition (Here, BINA-2 means Binasoybean-2 and BINA-6 means Binasoybean-6)

Total chlorophyll content was shapely decreased at saline condition (Fig. 15). The decreased rate was lower at lokon than other indicating its salt tolerance potentiality. Total chlorophyll content was relatively higher for the mutants SBM-22 and lower for SBM-26. From the visual salt injury score and chlorophyll content it was concluded that the mutants SBM-25 and SBM-26 was susceptible for salinity whereas Binasoybean-2, Binasoybean-6 and Lokon performed well and could be selected for the parent of stress breeding program.

## Growing of $\mathrm{M}_{\mathbf{5}}$ population

A large number of $\mathrm{M}_{5}$ populations from Lokon were grown in plant progeny-rows for selecting desirable mutants at BINA HQ farm, Mymensingh. Sowing was done within first week of January. Spacing between rows was 30 cm and $7-10 \mathrm{~cm}$ between plants in a row. Recommended production packages like application of recommended doses of fertilizers, irrigation, weeding, thinning, etc. were followed to ensure normal plant growth and development. Data were considered for plant height, number of branches plant ${ }^{-1}$, number of pods plant ${ }^{-1}$ and number seeds pod $^{-1}$. From them primarily, a total of five mutants have been selected based on their agronomic performances for subsequent generations.

## Growing of $\mathbf{M}_{\mathbf{4}}$ population

A large number of $\mathrm{M}_{4}$ populations from Binasoybean-3, Binasoybean-2, BU Soybean-1 and Taiwan-141 were grown in plant progeny-rows for selecting desirable mutants at BINA HQ farm, Mymensingh. Sowing was done within first week of January. Spacing between rows was 30 cm and $7-10 \mathrm{~cm}$ between plants in a row. Recommended production packages like application of recommended doses of fertilizers, irrigation, weeding, thinning, etc. were followed to ensure normal plant growth and development. Data were considered for plant height, number of branches plant ${ }^{-1}$, number of pods plant ${ }^{-1}$ and number seeds pod ${ }^{-1}$. From them primarily, a total of nine mutants have been selected based on their agronomic performances for subsequent generations.

## Growing of $\mathrm{M}_{\mathbf{3}}$ population

A large number of $\mathrm{M}_{3}$ populations from AVRDC366 and BU soybean-2 were grown in plant progeny-row for selecting desirable mutants at BINA HQ farm, Mymensingh. Sowing was done within first week of January. Spacing between rows was 30 cm and $7-10 \mathrm{~cm}$ between plants in a row. Recommended production packages like application of recommended doses of fertilizers, irrigation, weeding, thinning, etc. were followed to ensure normal plant growth and development. Data were considered for plant height, number of branches plant ${ }^{-1}$, number of pods plant ${ }^{-1}$ and number seeds pod ${ }^{-1}$. From them primarily a total of 12 mutant variants have been selected based on their agronomic performances for subsequent generation.

## Growing of $\mathbf{M}_{\mathbf{2}}$ population

Five bulk population (150, 200, 250, 300 and 400 Gy of gamma rays using $50 \%$ and $75 \%$ attenuation) of salt tolerant soybean variety Lokon were grown in plant progeny-rows for selecting desirable mutants at BINA HQ farm, Mymensingh. Sowing was done within first week of January. Spacing between rows was 30 cm and $7-10 \mathrm{~cm}$ between plants in a row. Recommended production packages like application of recommended doses of fertilizers, irrigation, weeding, thinning, etc. were followed to ensure normal plant growth and development. Data were considered for plant height, number of branches plant ${ }^{-1}$, number of pods plant ${ }^{-1}$ and number seeds $\operatorname{pod}^{-1}$. From them primarily a total of 15 mutant variants have been selected based on their agronomic performances for subsequent generations.

## Growing of $\mathrm{M}_{1}$ population

To create genetic variability, seeds of soybean variety A-363, PK-416, YESOY-4, PM-78-6-3-13, HISW, LG-92P was irradiated with 150, 200, 250, 300 and 350Gy of gamma rays. Seeds were sown on January 2022 at BINA HQ farm, Mymensingh. This experiment was followed non-replicated design and sown separately (variety and dose wise). At maturity stage the survived plants produced seeds were harvested separately for growing $\mathrm{M}_{2}$ population.

## Maintenance of germplasm (mutants, local and exotic collections)

Thirty germplasms along with four stable mutants were grown at BINA HQ farm, Mymensingh. After harvest, seeds of all germplasms were collected and preserved as breeding materials for future breeding programme.

## Sunflower

## Evaluation of sunflower germplasms for utilization in varietal improvement program

Twenty-three sunflower germplasm collected from BARI were grown in plant progeny-rows at BINA Head Quarter farm, Mymensingh on 28 December 2021. The experiment was conducted in a non-replicated design and unit plot size was $24 \mathrm{~m}^{2}(4 \mathrm{~m} \times 6 \mathrm{~m})$ with 50 cm line to line spacing and 25 cm from plant to plant within a line. Recommended production packages i.e., application of fertilizers, irrigation, weeding, thinning etc. were followed to ensure normal plant growth and development. Data on plant height (cm), head diameter (cm) and seeds/head were taken from 5 randomly selected plants from each plot. Maturity period was counted when $90 \%$ heads were matured in a plot. Appropriate statistical analysis was performed for comparison of mean of each character.
Data was recorded on average plant height $(\mathrm{cm})$, head diameter $(\mathrm{cm})$ and seeds/head from 5 randomly selected plants of each plot. Recorded data were subjected to proper statistical
analyses and presented in the Table 79. On an average, maturity period ranged from 98 to 125 days. BD9328 required shortest maturity period of 98 days and BD9382 required the longest maturity period of 125 days. Plant height ranged from 122 to 204 cm . BD9385 produced the tallest plant $(204 \mathrm{~cm})$ followed by BD9382 (172cm). BD9340 and BD9359 were comparatively dwarf having 122 and 123 cm plant height. Head Diameter ( cm ) is one of the major yield contributing characters of sunflower, it was ranged from 10-20.2cm. Among the genotypes, BD9382 produced highest number of seeds head ${ }^{-1}$ (441) followed by BD9349 (408). Considering yield contributing traits lines BD9340, BD9359, BD9349, BD9396, BD9391, BD9382 and BD9358 have been selected for future varietal improvements program.

Table 79: Yield and yield attributes of sunflower germplasm

| Germplasm \& Check variety | Days to maturity | Plant height (cm) | Head Diameter (cm) | Seeds/Head (no.) |

## Growing of $\mathbf{M}_{\mathbf{4}}$ generation of sunflowers

Twenty-three sunflower mutants and ten selected germplasm with three checks BARI Surjomukhi-2, BARI Surjomukhi-3 and Hycan-33 were used in this experiment. Mutants and germplasm were grown in plant progeny-rows at BINA Head Quarter farm, Mymensingh on 28 December 2021 following augmented block design. BARI Surjomukhi-2, BARI Surjomukhi-3 and Hycan-33 were included in each block with three replications. All the genotypes were sown in a non-replicated design and unit plot size was $24 \mathrm{~m}^{2}(4 \mathrm{~m} \times 6 \mathrm{~m})$ with

50 cm line to line spacing and 25 cm from plant to plant within a line. Recommended production packages i.e., application of fertilizers, irrigation, weeding, thinning etc. were followed to ensure normal plant growth and development. Data on plant height ( cm ), head diameter (cm) and seeds/head were taken from five randomly selected plants from each plot. Maturity period was counted when $90 \%$ heads were matured in a plot. Percent protein content was determined on the basis of total nitrogen content (from soil science division). Appropriate statistical analysis was performed for comparison of mean of each character.
The key yield contributing characteristics of sunflowers are plant height, Head diameters, hundred seed weight and seeds plant ${ }^{-1}$. All of the genetic parameters with the coefficient of variation, heritability and genetic advancement for the intended characteristics presented in Table 15. The highest phenotypic component of variance was found for number of seeds, filled grain and unfilled grain ( $124434.80,53079.61 \& 53539.76$ ), followed by leaf area and plant height ( $1846.79 \& 545.15$ ), where the lowest magnitude of phenotypic component of variance was observed in seed length ( 0.01 ) followed by plant diameter ( 0.20 ). Phenotypic coefficient of variance was greater than Genotypic coefficient of variance for each characteristic, and it was highest for unfilled grain ( $77.44 \& 84.22$ ). Number of filled grain, seed wt. plant ${ }^{-1}$, and total seeds plant ${ }^{-1}$ ( $94.03,936.83 \& 92.18$, respectively) had the highest heritability.

Data on days to maturity, plant height, head diameter, total no. of seeds, filled and unfilled grain and hundred seed wt. were taken and presented in Table 81. On an average, maturity period ranged from 91 to 139 days. DP150(1) required shortest maturity period of 91 days and LP350(4) required the longest maturity period of 139days. Plant height ranged from 94.21 to 209.31 cm . DP150(2), DP150(2), DP250 were the dwarf plant having plant height below 100 cm . Head Diameter ( cm ) is one of the major yield contributing characters of sunflowers, it was ranged from $11.84-22.51 \mathrm{~cm}$, whereas fill grain head ${ }^{-1}$ range from 164-
1103. The protein content of the selected genotypes was ranged from $19.27 \%$ tol3.41\%. Maximum protein was recorded from B10 followed by B11.

## Growing of $\mathbf{M}_{3}$ to $\mathbf{M}_{\mathbf{2}}$ generation of sunflower mutants

A large number of $\mathrm{M}_{3}$ and $\mathrm{M}_{2}$ variants developed from different irradiated materials were grown for selecting desirable mutant at BINA Head Quarter farm, Mymensingh. The seeds were sown on $20-26^{\text {th }}$ December 2021. All the seeds were space planted in 3 m long five rows with 50 cm row and 30 cm plant spacing. Recommended fertilizer was applied and necessary steps were taken to grow the crop uniformly.

Total 120 segregating population was evaluated for yield and yield contributing characters. Among them 85 was segregating families and other 35 was single plant. All of the segregating populations were obtained from $\mathrm{M}_{2}$ population that have been selected from previous trials, whereas single plant population was from earlier $\mathrm{M}_{1}$ population. A total of three families from $\mathrm{M}_{3}$ and seven families from $\mathrm{M}_{2}$ was selected and mass for future generation advancement. The selection was facilitated considered the maturity period (90-105 days) with other yield contributing characters. From various early generation single plant also selected considering maturity period, seed color, no. of seeds per head, head diameter and other agronomic traits. Fifty single plant have been selected and harvested separately for future utilization of varietal improvement program. From the variant population a total of 60 true breeding mutants also been selected primarily for further selection that will be grown respective advance generation on the basis of their agronomic performances.

## Growing of $M_{1}$ generation of sunflower

The well dried seed of BARI Surjomukhi-3 was used here. Ten seeds were exposed to 6 doses of EMS $(0.2 \%, 0.4 \%, 0.6 \%, 0.8 \%$ and $1 \%)$. Prior to mutagenic treatment seeds were kept in desiccators for moisture equilibration. The seeds were subjected to chemical mutagen for 12 hours. The response variables, percent germination ( $\% \mathrm{G}$ ) and percent survival ( $\% \mathrm{~S}$ ) rate were estimate after 21 days of sowing. The highest seed germination percentage occurred with doses of 0.2 and $0.4 \%$ EMS, whose values were $78 \%$ and $58 \%$, respectively decrease
progressively as the mutagenic dose was increased (Figure 17). Percentage of survival was a consequence of percentage germination. As the dose increased from 0.6 to $1.0 \%$, the percentage of survival was decreased, indicating that sunflower also a sensitive species at high levels of radiation (Figure 5). In the present investigation, we found that at the doses of $0.5 \%$ EMS, near about $50 \%$ of the population dies. Therefore, does near about $0.5 \%$ chemical mutagen may be use for the genetic variability in sunflower.

Fig 17: Germination (a) and survival percentage (b) of sunflowers seedlings subjected to five levels of EMS

## Programme Area: Varietal Improvement of Pulse Crops Project: Varietal improvement of mungbean using mutation breeding techniques

## On-farm \& on-station yield trial of promising summer mungbean mutant

The mung bean (Vigna radiata L.), commonly known as green gram, is a long-cultivated pulse crop that originated in South East Asia and is a member of the Papilionoideae family. Mung beans are primarily farmed for human consumption. It can be eaten as a vegetable or as cooked. Thus, it has great value as food and fodder. It is a cheap source of protein for human consumption. Mung bean has special features such as its earliness in maturity, supply of good yield, drought-resilient property that makes it highly responsive in scanty rainfall. Moreover, due to short duration, it can fitted well in cropping pattern. Objectives of this research are to evaluate the overall performance of the mutant for earliness, disease tolerance and seed yield. For this experiment, the mutant line MBM-656-51-2 with the check varieties Binamoog-8 and BARI Mung-6 were used during Kharif-1 season of 2022 at different locations (BINA
sub-stations Ishwardi, Magura 7 farmer's field Natore). The experiment was followed RCB design with three replications. The size of unit plot was $5.0 \mathrm{~m} \times 6.0 \mathrm{~m}$. Row to row and plant to plant distances were 40 and $10-15 \mathrm{~cm}$, respectively. Data on days to maturity, plant height, pods plant ${ }^{-1}$, pod length, seeds pod ${ }^{-1}$ and seed yield (tha-1) were recorded. Maturity was assessed plot basis. The data for the characters under study were statistically analyzed wherever applicable. Data were analyzed using Minitab statistical package.
Results revealed that significant variations were observed among the mutant and the check varieties at different locations. It was observed from the Table 82 that, the check variety MBM-656-51-2 had shorter plant height than the check varieties at all the locations. From mean over locations, the tested mutant matured earlier (62.3c days) than check varieties. The highest number of pods plant ${ }^{-1}$ (16.9a) was found in MBM-656-51-2. In respect of seed yield, this mutant produced the highest seed yield of 1.76a tha ${ }^{-1}$ followed by BARI Mung-6 (1.47c tha ${ }^{-1}$ ) and Binamoog-8 ( $1.68 \mathrm{bt} / \mathrm{ha}$ ). It will be registered to release this mutant (MBM-656-512) as a variety. Based on the present findings, it can be concluded that, the line MBM-656-512 can ensure better yield with the highest economic return for the farmers in the study area. Further evaluation of the line MBM-656-51-2 can be helpful to be registered as short duration mungbean variety.

## Evaluation of summer mungbean lines for synchronous pod maturity with yield

Despite the importance of synchronous maturity, mungbean pod ripening is not synchronous. Uneven pod maturity leads to low yield and low harvesting index (HI) inmungbean. A high harvest index means high proportion of total biomass production. Thus in order to increase the seed yield, selection of higher harvest index genotypes could be achieved through synchronous maturity. The inverse effects on seed yield due to high leafiness and asynchronous flowering have been observed.

Opportunities further exist to investigate potential synchronously maturing mutants in mungbean through induced mutagenesis. Such induced mutagenesis could help mungbean to be accepted as the main pulse crop in Asian countries in high fertile lands and sufficient without completing directly with major crops like wheat, rice and cotton. The objective of this experiment was to investigate the synchrony in pod maturity with highest yield potential of mungbean

With a view to identify earliness, synchronous pod maturity, disease tolerant and higher yielding mutant(s) MB-03, MB-07, MB-26 and MB-32 and two check variety varieties (Binamoog-8, BARI Moog-6) were sown at 23 February, 2022 at BINA substation, Barishal; 02 March, 2022 at BINA substation farm Magura; and 21 March, 2022 at BINA substation, Ishwardi. The experiment was conducted in RCB design with three replications. The size of the unit plots were $4.0 \mathrm{~m} \times 3.0 \mathrm{~m}$. Recommended doses of nitrogen, phosphorus, potassium, sulphur and zinc were applied form Urea, TSP, MoP, Gypsum and Zinc Sulphate. Cultural and intercultural practices were followed as and when necessitated. Data on duration, plant height, number of branch plant ${ }^{-1}$, number of mature pods plant ${ }^{-1}$, number of immature pods plant ${ }^{-1}$, Pod length (cm), number of seeds pod ${ }^{-1}$, 100 seed wt. (g.), and plot yield (g) were recorded after harvest from 5 randomly selected competitive plants. Maturity was assessed plot basis. Plot yield was recorded to t/ha. Finally, all the recorded data were subjected to proper statistical analyses as per design used and are presented in Table 83.

The mutants MB-03, MB-07 and MB-32 gave lower plant height which ranged from 37.67, 37.93 and 40.20 cm respectively than the variety Binamoog-8 ( 46.60 cm ) and BARI Mung-6 $(41.16 \mathrm{~cm})$. Among the mutants, higher branch plant ${ }^{-1}$ was observed in Binamoog-8 (2.18) compared to the mutants MB-03 (1.23), MB-07 (1.53) and MB-32 (1.71). Mature pod was higher in the mutant MB-32 (13.27) comparing to the check variety Binamoog-8 (11.71) and

BARI Mung-6 (11.02). Immature pod was greater in the check variety Binamoog-8 (4.34) comparing to the mutant MB-03 (0.58), MB-07 (0.77) and MB-32 (1.47). Pod length was higher in the mutant MB-07 $(7.75 \mathrm{~cm})$ contrasting to the variety Binamoog-8 $(7.46 \mathrm{~cm})$ and BARI Moog-6 ( 7.50 cm ). Maximum seeds pod $^{-1}$ was found in the check variety BARI mung6 (11.47) comparing to the mutant MB-03, MB-07 and MB-32 (11.28, 10.57 and 10.33 respectively). Higher 100 seed weight ( 4.92 g ) was found in the mutant MB-32 comparing to the Binamoog-8 and BARI Mung-6 (4.32 and 4.63 respectively). Higher yield was obtained from the mutant MB-03 (1.68 t/ha) comparing to the check variety Binamoog-8 (1.61 t/ha) and BARI Mung-6 ( 1.57 ton/ha). The mutant MB-03 had shorter duration (67 days) than the variety Binamoog-8 (69 days) and BARI Moog-6 (71 days).

Considering the earliness, synchronous pod maturity and yield performance of the mutant further advanced trial will be needed at next Kharif-I season

## Growing $\mathrm{M}_{\mathbf{4}}$ generation of mungbean for synchronous pod maturity

For synchronous pod maturity, seeds of Binamoog-8 variety were irradiated with Cobalt ${ }_{60}$ gamma rays. Irradiation doses were $10,20,40,60$ and 80 Gy . A large number of $\mathrm{M}_{4}$ population were grown in plant progeny rows for selecting desirable mutant at BINA sub-station Ishurdi during Kharif-I season 2022. A total of 10 mutant variants have been selected primarily for next generation.

## Growing $\mathrm{M}_{1}$ generation of mungbean for synchronous pod maturity

To create genetic variability, seeds of four popular mungbean varieties (Binamoog-5, Binamoog-8, Binamoog-9 \& Binamoog-10) were irradiated with with Cobalt ${ }_{60}$ gamma rays at 300, 350, 4007 450Gy doses. Seed were sown at BINA HQ farm, Mymensingh during Kharif-I season 2022. The experiment was followed by non-replicated design and sown separately (variety and dose wise). Survived plants produced seeds and seeds were harvested separately for growing $\mathrm{M}_{2}$ population.

## Project: Varietal improvement of lentil through induced mutation <br> On-station yield trial with four promising lentil mutants along with a check variety

On-stations yield trials were conducted with four mutant lines along with a check variety, Binamasur-8 at BINA sub-stations Chapainwabganj, Ishurdi and BINA headquarters farm, Mymensingh during 2021-2022. The experiment was laid out in a randomized complete block design with three replications. Unit plot size was $20 \mathrm{~m}^{2}(4 \mathrm{~m} \times 3 \mathrm{~m})$ with 30 cm line to line distance. Recommended production packages i.e., application of fertilizers, weeding, thinning, irrigation, application of pesticide etc. were followed to ensure normal plant growth and development. Data on days to maturity, plant height, number of primary branches plant ${ }^{-1}$ and pods plant ${ }^{-1}$ were recorded from 10 randomly selected plants from each plot. Plot seed yield was converted into $\mathrm{kg} \mathrm{ha}^{-1}$. Statistical analysis of different characters of the mutants and the check are presented in the Table 84.

Results revealed that significant variations were observed among the mutants and the check variety for days to maturity, pods per plant ${ }^{-1}, 100$-seed weight and seed yield at the three locations except number of primary branches per plant. On an average, maturity period varied from 102 days to 114 days. LM-99-8 produced the highest number of pods plant ${ }^{-1}$ and LM-$20-4$ produced the highest seed yield $1920 \mathrm{~kg} \mathrm{ha}^{-1}$ followed by LM-99-8 with $1825 \mathrm{~kg} \mathrm{ha}^{-1}$ at Chapainwabganj. In case of 100 -seed weight, higher weight was found in LM-20-4 followed by LM-88-9 at Ishurdi. Mutant LM-20-4 and LM-99-8 had the highest 100 -seed weight and produced the highest seed yield at Mymensingh. When combined over the three
locations, the line LM-20-4 produced the highest seed yield followed by the mutant LM-99-8. Further trials will be conducted in the next season.

## On-farm yield trial with some selected lentil mutants

On-farm yield trials were conducted with three mutant lines along with a check variety Binamasur-8 at farmers' field, Magura, Ishurdi and Chapainwabganj during 2021-2022. The experiment was laid out in a randomized complete block design with three replications. Unit plot size was $20 \mathrm{~m}^{2}(5 \mathrm{~m} \times 4 \mathrm{~m})$ with 30 cm line to line distance. Recommended production packages i.e., application of fertilizers, weeding, thinning, irrigation, application of pesticide etc. were followed to ensure normal plant growth and development. Data on days to maturity, plant height, number of primary branches plant ${ }^{-1}$ and pods plant ${ }^{-1}$ were recorded from 10 randomly selected plants from each plot. Plot seed yield was converted into $\mathrm{kg} \mathrm{ha}^{-1}$. Statistical analysis of different characters of the mutants and the check are presented in the Table 85.

Results revealed that significant variations were observed among the mutants and the check variety for most of the characters except plant height and primary branches per plant at the three locations. On an average, maturity period varied from 100 days to 105 days for the mutant LM-99-8 and LM-206-5 respectively. LM-99-8 produced the highest number of pods plant ${ }^{-1}$ as well as the highest seed yield $1769 \mathrm{~kg} \mathrm{ha}^{-1}$ and also LM-20-4 produced the same seed yied of $1769 \mathrm{~kg} \mathrm{ha}^{-1}$ followed by the mutant LM-118-9 with $1681 \mathrm{~kg} \mathrm{ha}^{-1}$ at Magura. The mutant LM-206-5 produced the highest seed yield ( $1821 \mathrm{~kg} \mathrm{ha}^{-1}$ ) followed by the mutant LM-20-4 (1799 $\mathrm{kg} \mathrm{ha}^{-1}$ ) at Ishurdi. The same line LM-20-4 produced the highest seed yield (1800 $\mathrm{kg} \mathrm{ha}^{-1}$ ) followed by the mutant LM-99-8 (1799 $\mathrm{kg} \mathrm{ha}^{-1}$ ) at Chapainowabganj. When combined over the three locations, The line LM-20-4 and the mutant LM-99-8 produced the highest seed yield. Further trial will be conducted in the next season.

## Advanced yield trial with some selected mutants of lentil

The advanced yield trials were conducted with five mutants along with a check variety, Binamasur-8 at Mymensingh during 2021-2022. Seeds were sown in randomized complete block design with three replications. Unit plot size was $3 \mathrm{~m} \times 2 \mathrm{~m}$ and rows were 30 cm apart.

Normal cultural practices were done. Data on days to maturity, plant height, number of primary branches, pods plant ${ }^{-1}$ were recorded from 10 randomly selected plants from each plot. Plot seed yield was converted into $\mathrm{kgha}^{-1}$. Statistical analysis of different characters of the accessions and the check are presented in the table 86.

Results revealed that significant variations were observed among the mutants and the check variety for most of the characters except number of primary branches per plant. On an average, maturity period varied from 90 days to 95 days where the mutant LM-250 was the earliest among the mutants and the check variety. The mutant LM-300 and LM-150 produced the highest number of pods plant ${ }^{-1}$ followed by LM-250 and the highest seed yield was produced by LM-300 (1698 $\mathrm{kgha}^{-1}$ ) followed by LM-150 (1670 $\mathrm{kgha}^{-1}$ ). Further trial will be conducted in the next season at different lentil growing areas.

Table 86. Yield and yield contributing characters of five promising mutants along with a check variety, Binamasur-8 at Mymensingh during 2021-22

| Variety/ <br> mutant | Days to <br> maturity | Plant <br> height <br> $(\mathbf{c m})$ | Primary <br> Branches/ <br> plant (no.) | Pods/plant <br> (no.) | Yield <br> (kg/ha) |

| LM-300 | 95 a | 32.9 ab | 2.62 | 115 a | 1698 a |
| Binamasur-8 | 94 a | 32.3 ab | 2.31 | 56 c | 1401 c |

## Growing of $\mathbf{M}_{6 /} \mathbf{M}_{5}$ generation of lentil

A total of $12 \mathrm{M}_{4}$ plants were harvested from four doses, $150 \mathrm{~Gy}, 200 \mathrm{~Gy}$ and 250 Gy . Seeds of these $\mathrm{M}_{4}$ plants were grown in plant-progeny-rows at BINA headquarters farm Mymensingh along with the mother variety. Another set of $17 \mathrm{M}_{5}$ lines were grown at BINA headquarters farm Mymensingh. Each row was 2 m long with 30 cm row to row distance.
Normal cultural practices were done. Selection was done on the basis of earliness, number of pods plant ${ }^{-1}$, seed yield and erect plant type and disease reactions. Altogether $19 \mathrm{M}_{5}$ and four $\mathrm{M}_{6}$ lines were selected on the basis of higher yield, earliness and disease reactions. These lines will be grown for further selection in the next generation.

Screening of exotic lentil lines for early maturity, disease tolerance and higher seed yield
Around 280 lentil lines were collected from ICARDA. To select desirable lines with early maturity, high yield and tolerance to diseases, an experiment was set up at BINA regional research station, Gazipur and BINA Sub-station Magura during Rabi 2021-2022. 29 lines were screened based on their yield and yield contributing characters.

## Project:Varietal improvement of blackgram through induced mutation

## On-station yield trial with two promising blackgram mutants along with a check variety

The trials were conducted with two promising blackgram mutants along with a check variety. BARI Mash-3 at BINA substations Magura, Chapainawbabganj, Gopalganj and BINA
headquarters farm Mymensingh during 2021. The experiment was laid out in a randomized complete block design with three replications. Unit plot size was $20 \mathrm{~m}^{2}(4 \mathrm{~m} \times 3 \mathrm{~m})$. Plant to plant distance was from 5 to 6 cm in a row while line to line distance was 40 cm . Intercultural operations; like weeding, thinning, application of pesticides, etc. were done for proper growth and development of plants in each plot. Harvesting was done depending on maturity of the lines. Data on various characters as plant height, number of primary branches plant ${ }^{-1}$, pods plant ${ }^{-1}$, number of seeds pod ${ }^{-1}, 100$-seed weight were recorded from 10 randomly selected plants of each plot. Seed yield plot plot ${ }^{-1}$ was recorded and converted into kg ha ${ }^{-1}$. Appropriate statistical analyses were performed by statiatics-10 software.

Table 87. Mean of yield and yield contributing characters of two promising mutants of blackgram grown at four locations Magura, Mymensingh, Chapainawbganj and Gopalganj during 2021

| Variety | Plant height (cm) | Primary branches / plant (no.) | Pods/plant (no.) | Seeds/pod (no.) | 100-seed weight (g) | $\begin{gathered} \text { Seed } \\ \text { Yield } \\ (\mathbf{k g} / \mathrm{ha}) \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| BM-63 | 45.51a | 2.34ab | 41.93ab | 5.30 b | 4.56b | 1466b |
| BARI Mash-3 | 42.12ab | 1.97b | 30.5b | 6.30b | 4.21b | 1461b |
| Combined over four locations |  |  |  |  |  |  |
| BM-105 | 41.44 | 3.11 | 49.37 | 6.75 | 5.75 | 1817a |
| BM-63 | 47.55 | 2.30 | 41.42 | 5.73 | 4.47 | 1568b |
| BARI Mash-3 | 44.94 | 2.17 | 31.90 | 5.65 | 4.28 | 1552b |

Results revealed that there were significant differences for most of the characters except number of primary branches at Magura. BM-105 was the shortest among the mutants and check at Magura, Mymensingh, Chapainwabganj and Gopalganj. In case of primary branches per plant, BM-105 had the highest number of branches, seeds pod ${ }^{-1}$ and 100 -seed weight among the check variety, BARI Mash-3 the other mutant BM-63. Seed yield was the highest for BM-105 because of its bigger seed size and higher number of pods plant ${ }^{-1}$. Application will be made to register this mutant line as variety soon.

## On-farm yield trial with two promising blackgram mutants along with a check variety

The trial was conducted with two promising blackgram mutants along with a check variety. BARI Mash-3 at three locations, Mymensingh, Faridpur and Gopalganj during 2021. The experiment was laid out in a randomized complete block design with three replications. Unit plot size was $20 \mathrm{~m}^{2}(5 \mathrm{~m} \times 4 \mathrm{~m})$. Plant to plant distance was from 5 to 6 cm in a row while line to line distance was 40 cm . Intercultural operations such as weeding, thinning, application of pesticides, etc. were done for proper growth and development of plants in each plot. Harvesting was done depending on maturity of the lines. Data on various characters as plant height, number of primary branches plant ${ }^{-1}$, pods plant ${ }^{-1}$, number of seeds pod ${ }^{-1}, 100-$ seed weight were taken from 10 randomly selected plants of each plot. Seed yield plot $^{-1}$ was recorded and converted into $\mathrm{kg} \mathrm{ha}^{-1}$. Appropriate statistical analyses were performed by statiatics-10 software.

Table 88. Mean performance of mutants along with a check variety BARI Mash-3 at three locations, Mymensing, Magura and Faridpur during 2021

| Variety | Plant height (cm) | Primary branches / plant(no. ) | Pods/plant (no.) | Seeds/pod (no.) | 100-seed weight (g) | $\begin{gathered} \text { Seed } \\ \text { Yield } \\ (\mathbf{k g} / \mathrm{ha}) \end{gathered}$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Mymensingh |  |  |  |  |  |  |  |
| BM-105 | 39.52b | 2.60 | 39.12 a | 5.10b | 5.62 a | 1642a |  |
| BM-63 | 47.48a | 2.3 | 28.51b | 7.33a | 4.31b | 1590ab |  |
| BARI Mash-3 | 41.20 b | 2.14 | 27.42b | 4.20b | 4.25b | 1563b |  |
| Magura |  |  |  |  |  |  |  |
| BM-105 | 36.21b | 2.66 | 42.32a | 4.51b | 5.51a | 1699a |  |
| BM-63 | 43.63a | 2.32 | 36.21ab | 5.52b | 3.56b | 1543b |  |
| BARI Mash-3 | 38.20 b | 2.11 | 29.21b | 5.61a | 4.47a | 1572b |  |
| Faridpur |  |  |  |  |  |  |  |
| BM-105 | 39.42a | 2.64 | 35.11a | 5.51b | 6.21a | 1485a |  |
| BM-63 | 45.31b | 2.20 | 26.25 b | 6.11a | 4.11c | 1319b |  |
| BARI Mash-3 | 43.11b | 2.12 | 27.04b | 4.71b | 5.13b | 1308b |  |
| Combined over locations |  |  |  |  |  |  |  |
| BM-105 | 38.38 | 2.63 | 38.85 | 5.04 | 5.78 | 1608 |  |
| BM-63 | 45.47 | 2.27 | 30.32 | 6.32 | 3.99 | 1484 |  |
| BARI Mash-3 | 40.83 | 2.12 | 27.89 | 4.84 | 4.62 | 1481 |  |

Results revealed that there were significant differences for most of the characters among the tested mutants and the check variety except plant height and number of branches per plant (Table 87). The mutant, BM-105 was the shortest among the mutants and check. The mutant line BM- 105 had the highest number of pods plant ${ }^{-1}$, seeds pod ${ }^{-1}$ and 100 -seed weight among the mutant and the check variety, BARI Mash-3. Seed yield was the highest for BM-105 because of its bigger seed size and higher number of pods plant- ${ }^{1}$. This mutant will be registered as variety soon.

## Advanced yield trial with promising blackgram mutants

The trials were conducted with six promising blackgram mutants along with a check variety, BARI Mash-3 at Chapainwabganj. The experiment was laid out in a randomized complete block design with three replications. Unit plot size was $2 \mathrm{~m} \times 1.6 \mathrm{~m}$. Plant to plant distance was from 5 to 6 cm in a row while line to line distance was 40 cm . Intercultural operations like weeding, thinning, application of pesticides, etc. were done for proper growth and development of plants in each plot. Harvesting was done depending on maturity of the lines. Data on various characters as plant height, number of primary branches plant ${ }^{-1}$, number of seeds $\operatorname{pod}^{-1}, 100$-seed weight were recorded from 10 randomly selected plants of each plot. Seed yield plot ${ }^{-1}$ was recorded and converted into $\mathrm{kg} \mathrm{ha}^{-1}$. Appropriate statistical analyses were performed by statistics 10 .

Table 89. Mean of yield and yield contributing characters of 10 promising mutants of blackgram at Chapainwabganj during 2021

| Variety |  | Plant <br> height <br> (cm) | Primary <br> branches/ <br> plant <br> (no.) | Pods/plant <br> (no.) | Seeds/pod <br> (no.) | 100-seed <br> weight <br> (g) | Seed <br> yield <br> $(\mathbf{k g} / \mathbf{h a})$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| BM-235 | 36.22 b | 1.57 | 28.9 a | 5.4 ab | 4.92 a | 1236 ab |  |
| BM-46 | 31.71 ab | 1.70 | 29.9 a | 6.3 a | 4.91 a | 1350 a |  |
| BM-42 | 27.90 c | 2.31 | 23.2 ab | 4.7 b | 3.24 b | 1152 bc |  |
| BM-41 | 25.6 c | 2.06 | 19.7 b | 4.6 b | 4.57 a | 1040 |  |
| BM-4 | 27.6 c | 1.61 | 20.2 b | 6.1 a | 4.89 a | 1192 bc |  |
| BARI Mash-3 | 42.02 a | 1.63 | 23.4 ab | 5.4 ab | 4.27 a | 1072 c |  |

Results revealed that there were significant differences for most of the characters except number of branches per plant. BARI Mash-3 was the tallest among the mutants and the check. In case of number of pods plant ${ }^{-1}$ BM-235 and BM-46 had the highest number of pods plant ${ }^{-1}$ among the other mutants and the check variety, BARI Mash-3. The highest number of seeds pod ${ }^{-1}$ and the highest 100 -seed weight was observed in BM-235 and BM-46 followed by BM-4. Seed yield was the highest for BM- 46 followed by BM- 235 because of their higher number of pods plant ${ }^{-1}$, seeds pod ${ }^{-1}$ and 100 -seed weight. Further trials will be done with the three selected mutants BM-235, BM-46 and BM-4 for further evaluation.

## Growing of $\mathrm{M}_{2}$ generation of blackgram

To create variability local variety Chaita was irradiated with $600 \mathrm{~Gy}, 700 \mathrm{~Gy}$ and 800 Gy of gamma rays and were grown at BINA headquarters farm. There were no better mutants in respect of earliness, higher seed yield and erect plant type.

## Project: Varietal improvement of grasspea through induced mutation

## On-station yield trial with three promising grasspea mutants along with the two check

 varietiesThe on-station yield trials were carried out with three selected mutants along with two check varieties (Binakheshari-1 and BARI khasari-2) at BINA sub-stations Chapaianwabganj and Barishal during 2021-2022. The experiment was conducted in randomized complete block design with three replications. Unit plot size was $3 \mathrm{~m} \times 2 \mathrm{~m}$ with 40 cm row to row distance. Normal cultural practices were done. Data on days to maturity, plant height, primary branches plant ${ }^{-1}$, pods plant ${ }^{-1}$ and 100 -seed weight were recorded from 10 randomly selected plants from each plot. Plot seed yield was converted into $\mathrm{kgha}^{-1}$. Statistical analysis of different characters of the mutants and the check are presented in the Table 90.

Results revealed that significant variations were present for all the characters except number of primary branches plant ${ }^{-1}$ at all the locations. It was observed that mutant GM-102 was the earliest for maturity and it is the tallest plant among the mutants and checks. The mutant GM108 and GM-102 produced the highest number of pods and highest seed yield at Chapainwabganj followed by the mutant GM-105. The same mutant GM-108 produced the highest number of pods and the highest seed yield at Barishal. Based on the better performance of the mutant line GM-108 has been registered as a variety, Binakhesari3 in 2022.

## On-farm yield trial with three promising grasspea mutants along with two check varieties

The on-farm yield trials were carried out with three selected mutants along with two check varieties (Binakheshari-1 and BARI khasari-2) at farmers' field, Ishurd, Chapainwabganj, Magura and Barishal during 2020-2021. The experiment was conducted in a randomized complete block design with three replications. Unit plot size was $3 \mathrm{~m} \times 2 \mathrm{~m}$ with 40 cm row to row distance. Normal cultural practices were done. Data on days to maturity, plant height, primary branches plant ${ }^{-1}$, pods plant ${ }^{-1}$ and 100 -seed weight were recorded from 10 randomly selected plants from each plot. Plot seed yield was converted into $\mathrm{kgha}^{-1}$. Statistical analysis of different characters of the mutants and the check are presented in the Table 91.

Results revealed that significant variations were found for all the characters except number of primary branches plant ${ }^{-1}$. It was observed that mutant GM-102 was the earliest for maturity and it was the tallest plant among the mutants and checks. The mutant GM-108 produced the highest number of pods and highest seed yield followed by the mutant GM-105. The better performed mutant, GM-108 has been registered as a modern high yielding variety, Binakhesari3 in 2022.

Table 91. Mean of yield and yield contributing characters of four promising mutants of grasspea at grown at four locations during 2021-2022

| Varieties/ mutants | Days to maturit y | Plant height (cm) | No of primary branch | No of pods /plant ${ }^{-1}$ | 100-seed weight (gm) | Seed yield (kgha ${ }^{-1}$ ) |

## Regional yield trial with five promising grasspea mutants along with two check varieties

The on-farm yield trials were carried out with six selected mutants along with a check variety BARI khasari-2 at BINA headquarters farm, Mymensingh during 2021-2022. The experiment was conducted in a randomized complete block design with three replications. Unit plot size was $3 \mathrm{~m} \times 2 \mathrm{~m}$ with 40 cm row to row distance. Normal cultural practices were done. Data on days to maturity, plant height, primary branches plant ${ }^{-1}$, pods plant ${ }^{-1}$ and 100 -seed weight were recorded from 10 randomly selected plants from each plot. Plot seed yield was converted into $\mathrm{kgha}^{-1}$. Statistical analysis of different characters of the mutants and the check are presented in the Table 92.

Results revealed that significant variations were found for all the characters except number of primary branches plant ${ }^{-1}$. It was observed that mutant GM-304 was the earliest for maturity (103days) and it was the shortest plant among the mutants and check. The mutant GM-304 produced the highest number of pods and highest seed yield followed by the mutant GM-305 and GM-309. The three mutants, GM-304.GM-305 and GM-309 will be evaluated in the next growing season.

## Growing of $\mathbf{M}_{5}$ generation of grasspea

To create variability, Binaheshari-1 and BARI Kheshari-2 were irradiated with $250 \mathrm{~Gy}, 300$ Gy and 350 Gy of gamma rays and were grown at BINA Headquarters farm, Mymensingh. A total of $120 \mathrm{M}_{2}$ plants were harvested separately from three doses, $250 \mathrm{~Gy}, 300 \mathrm{~Gy}$ and 350 Gy. and subsequent generation of selection was done on the basis of earliness, more number of pods and disease reactions. A total of $11 \mathrm{M}_{5}$ mutants were selected on the basis of earliness, more number of pods and disease reactions. Further selection will be done in the next generation.

## Screening of exotic grasspea lines for early maturity, disease tolerance and higher seed yield

Around 183 grasspea lines were collected from ICARDA. To select desirable lines with early maturity, high yield and tolerance to diseases, an experiment was set up at BINA regional research station, Gazipur and BINA Sub-station Magura during Rabi 2021-2022. 24 lines were screened based on their yield and yield contributing characters.

# Project: Varietal improvement of chickpea for problem areas through induced mutations 

## Screening of exotic Chickpea lines for early maturity, disease tolerance and higher seed yield

Around 279 chickpea lines were collected from ICARDA. To select desirable lines with early maturity, high yield and tolerance to diseases, an experiment was set up at BINA regional research station, Gazipur and BINA Sub-station Magura during Rabi 2021-2022. 29 lines were screened based on their yield and yield contributing character.

## Project: Varietal improvement of garden pea using mutation breeding techniques

## Growing $\mathbf{M}_{\mathbf{2}}$ generation of garden pea

Seeds of BARI Motor-3 was irradiated with Cobalt ${ }_{60}$ gamma rays. Irradiation doses were 20, 40, 60 and 80 Gy . Dose wise bulk seeds of each variety were grown at BINA Headquarters' farm during Rabi season 2021-2022. Fifteen mutant variants were selected based on bolder seed size, higher seed yield and disease tolerance for further evaluation.

## Project: Varietal improvement of pigeon pea using mutation breeding techniques (Collaboration with Plant Pathology and Entomology division)

## Growing of $\mathbf{M}_{3}$ generation of Pigeon pea

Seeds of three local pigeon pea germplasms were irradiated with $\mathrm{Co}_{60}$ gamma rays. Irradiation doses were 15, 20, 25 and 30Gy. Dose wise bulk seeds of each variety were grown at BINA Headquarter farm during July 2021. Seventeen mutant variants were selected based on shorter plant height, higher seed yield and disease tolerance for further evaluation.

## Collection and Growing of rice landraces for seed

Collection: During the period 2021-22 a total of 40 germplasm of different rice were collected from Farmers of Cumilla and DAE, Bandarban. Collectors visited those areas and recorded passport information of the germplasm at the time of collection. Seeds of different germplasm were cleaned, processed, dried and stored in short term storage of BINA Substation, Cumilla germplasm collection room for seed multiplication and characterization. One team such as * FA, was formed comprising 2 member. Each expedition was conducted for 1-2 days. The teams were equipped with ice box, plastic carton, GPS, compass, digital camera, hand lens, envelop, knife, scissors, drying sheet, pencil, stapler etc. Germplasm of target crops were collected from farmers' field/farm store/threshing floor and market especially from floating seed traders.

Targeted farmers for collection of specific germplasm were located with the help of field level worker of the Department of Agriculture Extension (DAE) and direct contact. Collector's name, number and date were recorded during collection. Name of crop species alongwith English, Bangla, local and cultivar name were recorded. Name of donor with ethnic group, village, union, upazila/thana, district, latitude and longitude were noted. Type of soil, topography, sample status, sample source, habitat, frequency, type of materials, cultural practices, season, sole or mixed with, sample type, sampling method, insect and disease, agronomic score and plant characteristics were noted. A 'Passport Data Form' having passport information was filled up during germplasm collection. The samples were registered in conservation book immediately after collection and conserved in short term
conservation storage of following appropriate procedure. Number of upazilas explored and number of germplasm collected from each district is shown in table 91. Passport information of collected germplasm of assigned crops is shown in Table 93
Table 93. Passport information of collected rice (Oryzae sativa) germplasm

## B. Characterization:

## Morphological Characterization of aromatic rice germplasm of Bangladesh.

Continuous effort is needed to develop high yielding rice varieties to feed the ever increasing population. Therefore, study of morphological characterization of the germplasm is very much essential to find the desirable traits to use as potential breeding tool. In this regard, forty two rice germplasm were evaluated to assess the variation considering 10 quantitative and 31 qualitative traits under field condition during the period from July to December 2021 at the BINA Substation, Cumilla following Randomized Complete Block Design (RCBD) with three replications. Qualitative characterization by DUS test revealed that a wide range of variation was observed among the studied germplasms for blade color, leaf angle, flag leaf angle, culm angle, internode color, culm strength, panicle exertion, axis, shattering, threshability, apiculus color, stigma color, lemma and palea color, lemma and palea pubescence, sterile lemma color, seed coat color and leaf senescence. Therefore, this study would be helpful for breeders and researchers to choose and identify the restoration and conservation of beneficial genes for crop improvement.

## Materials and Methods:

The experiment was carried out during the period from July to December 2021. In this study, 42 rice germplasm were used as plant materials. The list of the experimental materials along with their sources of collection is shown in Table 94.
Table 94. List of the rice germplasm included in the experiment

The experiment was carried out in Randomized Complete Block Design (RCBD) with three replications. Unit plot size was $2 \mathrm{~m} \times 2 \mathrm{~m}$. The seeds were soaked in water for 24 hours. Then it was incubated in moist cloth sacks for 48 hours for quick germination. The pre-germinated seeds were sown in seedbed on 14 July, 2021. When the seedlings were 25 days old, one seedling hill ${ }^{-1}$ was transplanted to the main plot on the 9 August, 2021. Spacing between hills and rows were 15 and 20 cm , respectively. Basal dose of TSP and MP at the rate of 45 kg and 25 kg per hectare was applied. After transplanting the recommended dose of Urea, 160 kg per hectare was top dressed at three growth stages of rice. Irrigation and drainage were done as per requirement. The crop was kept weed free throughout the growth period. Insects and fungal attacks were negligible. Different germplasm attained their maturity at different times. Harvesting was done when $80 \%$ of the plant population of each plot reached to maturity and harvesting was done from 20 October to 05 November, 2021. The experimental plots were visited frequently and as per schedule, required data were collected. A data record book was used for keeping records of data related to the identification of the germplasm. Data were recorded on individual plant basis from 5 randomly selected plants on the following qualitative and quantitative traits.

## Characterization based on qualitative characters by DUS test

A total of 37 rice land races were taken for DUS characterization using 42 characters which include 31 qualitative and seven quantitative characters as per BRRI descriptor (2018). The rice landraces undertaken for this study showed wide range of distinctiveness characters for all most all the morphological traits studied. Frequency distribution for all the characters under study was computed (in Table 95) and qualitative and quantitative characters of different agronomic and morphological parameters are given in Table 85 and 86.

Out of 42 germplasm studied, $90.48 \%$ germplasm didn't shown anthocyanin coloration of apex while only $9.52 \%$ exhibited the anthocyanin colouration on leaf sheath. In case of blade pubescence $69.05 \%$ germplasm exhibited glabrous, $28.57 \%$ exhibited intermediate and only one germplasm had shown pubiscent.

All most all the landraces were of green colored basal leaf sheath, among the germplasm only one germplasm (S-14) had purple green and 3 had light green basal leaf sheath color. With respect to leaf characters, among 42 germplasm, 36 had shown erect leaf angle, 5 had horizontal and one germplasm Lombaail had drooping type of leaf angle of main axis. In case of legule shape, most of the germplasm ( $95.25 \%$ ) had 2-cleft legule shape. For collar color and auricle color most of the germplasm were pale green. Anthocyanin color in culm was absent in 37 germplasm and present in 6 germplasm. Most of the germplasm ( $64.29 \%$ ) had erect culm angle, 9 had intermediate, 4 had open and 2 germplasm (Lalchini and Chinigura (D-8) had spreading culm angle. Among 42 germplasm, 23 germplasm had strong lodging resistance while 6 had shown very weak performance to lodging resistance. But at dough stage, $100 \%$ plants of 10 germplasm had lodged and the plants of 22 germplasm had not lodged. Compact and enclosed panicle was found in 8 germplasm (Malshira, Lalchini, Ojanabirun, Doiorgura-1, Nur basmati, Parbotjira, Khirsapati, and Basmati India). With respect to panicle characters, $23.81 \%$ germplasm were straight and $76.19 \%$ germplasm were of drooping type of panicle curvature of main axis.
In case of awn distribution, $71.43 \%$ germplasm recorded the absence of awns and 12 germplasm (i.e. Lalchini, Chinigura (D-8), Jirabuti, Meni, Vabmoti, ICSS-Balam TAPl-25, Votirchikon, Rajbuti, S-14, Chinigura-1, Tilokkhachori, Durgavog, Kalomala ) recorded the presence of awns. Out of which, six germplasm found straw, four germplasm were brown and
two germplasm had purple coloured awns. In stigma colour, $73.80 \%$ cultivars exhibited white stigma, $23.81 \%$ landraces were of light green stigma and $2.38 \%$ were of purple stigma.

With regard to colour of the lemma and palea, $47.48 \%$ of germplasm were straw colour, $33.33 \%$ germplasm recorded gold and gold furrows on straw background, $2.38 \%$ germplasm were of brown spots on straw, $2.38 \%$ germplasm were of brown furrows on straw, $4.76 \%$ germplasm were of brown, $4.76 \%$ germplasm were reddish to light purple, $2.38 \%$ germplasm were of brown (tawny), $4.76 \%$ germplasm were purple and $4.76 \%$ germplasm were of black. In case of density of pubescence of lemma, 32 germplasm exhibited short hairs, 2 germplasm with long hairs, 6 germplasm with hairs on lemma keel and 22 germplasm had no pubescence. All most all the landraces were of straw coloured sterile lemma, except for 7 germplasm, which have gold and purple colour sterile lemma. For the character seed coat (bran) colour of 11 germplasm were of white in colour, 13 germplasm were of light brown, 14 germplasm were of Speckled brown, 3 germplasm were of brown and 114 germplasm exhibited Variable purple type seed coat color. Non-glutinous (no waxy) endosperm was found in 11 germplasm, 22 germplasm had shown glutinous endosperm and 9 germplasm had shown Intermediate type endosperm. Aroma of decorticated grain was recorded in six germplasm, among them Parbotjira was lightly scented and 5 germplasm (Chinisail-47, ICSS-Balam TAPl-25, Nurbasmati, Deshikatari, Sadamota) were of highly scented

## Characterization based on quantitative characters by DUS test

Observed variables of quantitative characters of included seven traits and five plants from each replication of each germplasm were randomly selected for recording data on plant height (cm), Days to $50 \%$ flowering, Days to $80 \%$ of maturity, Number of effective tillers, Panicle length $(\mathrm{cm}), 100$ seed weight $(\mathrm{g})$, Grain yield $\mathrm{m}^{-2}$.
The tallest plant was recorded in Chinisail-47 ( 130.67 cm ) followed by Kalonunnia( 124.67 $\mathrm{cm})$ and Kalijira TAPL-7 ( 123.33 cm ) whereas the shortest plant was recorded in Padmavog $(82.00 \mathrm{~cm})$ followed by Doiorgura-1 $(84.00 \mathrm{~cm})$. Days to fifty $\%$ flowering ranged from 87.67 to 113.67 days. Among the studied germplasms, Kalijira M-13 took longest time (113 days) to $50 \%$ flowering followed by Chinisail-47 and Basmati-370 (112.67 days) while Basmati-2 ( 87.67 days) took the shortest time followed by Oval TAPL (88.33days).

The maturity ( $80 \%$ ) of the studied germplasm ranged 120.33-146.33 days. Shonajuri and Basmati-370 took the maximum time ( 146.33 days) to mature followed by Jotakatari (143.33 days), while Basmat-2 took only 120.33 days to mature followed by Kalijira TAPL-51 ( 124.33 days). Number of effective tillers per hill ranged 4.33 to 14.33 . Basmat-India had produce maximum number of effective tillers (14.33) followed by Khirsabuti (13.00) and Sadamota (12.67). On the other hand, S-14 had lowest number of effective tillers.

Kalijira TAPL-7 had the longest panicle ( 29.67 cm ) followed by Chinisail-47 ( 28.67 cm ), Chinisakkhor ( 28.33 cm ) and whereas Kalomala ( 15.33 cm ) had the shortest panicle. Among the studied rice germplasms, the highest grain yield $\mathrm{m}^{2}{ }^{2}$ was recorded in Doiorgura-1 (640.00
g) followed by Modhumadhob. The differences among the rice germplasms were also significant.

In this study, 100 -grain weight ranged from 0.84 g to 3.03 g with an average value of 1.83 g . The variation observed for this trait was highly significant. Hundred-grain weight was marked the highest in Tilokkhachori ( 3.03 g ) followed by durgavog ( 2.68 g ) whereas 100 grain weight was marked the lowest in Noor basmati $(0.84 \mathrm{~g})$.

## Biotechnology Division

## Research Highlights of Biotechnology Division

## Genetic Engineering and Tissue Culture

- In T. aman 2021 a total of 16,985 anthers were plated on three different type's media from two F1 generations. Finally, only 8 green plants were obtained from calli derived from F1 of Binadhan- $12 \times$ Kasalath cross.
- For development lodging resistance and high yield premium quality rice, 19 in vitro regenerated plants were obtained from calli treated with gamma rays.
- For development drought tolerant rice variety inducing PEG stress (5\%, 8\% and 10\%) on embryogenic calli and that found growth rate and regeneration capacity were decreased with increasing levels of PEG concentration.
- Salt stress imposed to 100 mM transgenic tomato plants showed higher fresh shoot and root weight compared to wild type plants. All transgenic plants retained higher Na+ content than the wild type. Increasing salt stress decreasing the chlorophyll content but the rate of decreasing was less compared to wild type.
- The MS medium supplemented with $2.0 \mathrm{mg} / \mathrm{L} 2,4-\mathrm{D}$ produced the maximum frequency of callus induction from matured embryo of BRRIdhan89. Eight $0.2 \%$ EMS regenerated mutants of BRRIdhan-89 were obtained yielding per plant ranges from 45 g to 115 g .
- A total of 11 genotypes were studied for improvement of high value sweet pepper genotypes in rabi season 2021. Finally, the four genotypes (CKN- 1, CKN- 2, CKN8 and CKN- 9) were selected for the further evaluation and subsequent genetic engineering and tissue culture research.
- The efficiency of callus and shoot initiation in hypocotyls explants of rapeseed was best achieved in MS medium containing BAP1 $1.0 \mathrm{mg} / \mathrm{L}+$ NAA $0.2 \mathrm{mg} / \mathrm{L}+\mathrm{GA} 3$ $0.02 \mathrm{mg} / \mathrm{L}+\mathrm{AgNO} 31.0 \mathrm{mg} / \mathrm{L}$. The shoot regeneration and shoot elongation occurred on MS medium containing with BAP2 $0.00125 \mathrm{mg} / \mathrm{L}$ + adenine hemisulfate $40 \mathrm{mg} / \mathrm{L}$ + PVP $500 \mathrm{mg} / \mathrm{L}$.

## Marker Assisted Selection:

- For tidal submerged tolerant rice variety development three F5 and twelve M4 mutant lines were selected in T aman 2021 for further evaluation.
- For high yield and short duration rice variety development thirteen materials were grown with three standard checks In Boro (BRRI dhan96), 2021-22. The line Bina(bio)-BC2-5-2-3-14 produced the higher yield ( $9.05 \mathrm{t} / \mathrm{ha}$ ) followed by line Bina(bio)-BC2-5-2-11-2-33 (8.82 t/ha) and line Bina(bio)-BC2-5-2-3-50 (8.65 t/ha).
- For premium quality rice variety improvement about 100 F 3 plants were selected from 25 segregating F3 populations in T. aman 2021 and Boro, 2021-22. Twenty nine F4 (Kataribhog x Oryza rufipogon) lines/plants were selected on the basis of better plant types compare to the parents.

## Microbial Biotechnology:

- We assessed the growth and production of pea, lentil, and lathyrus in soils using three native strains (BL129, BL153, and BL460). Inoculation of pea with indigenous strain BL460, inoculation of lentil with strain BL129 and inoculation of lathyrus with strain BL460 recorded higher grain yields than all other treatments. Inoculation of indigenous mixed strains also resulted in significantly higher pea, lentil, and lathyrus grain yields than control.
- Three bacterial isolates designated as CD1A, CD2A and CD3 were used with $50 \%$ recommended dose of fertilizer were found better in producing effective tillers per hill, filled grain per panicle and grain yield per plant. The present study, therefore, suggests that these bacterial isolates could be used as bio-fertilizers for reducing the use of chemical fertilizers, enhancing growth and yield of rice at field conditions.
- Three strains (TAN-2, TAN-8 and TAN-10) combat the As toxicity in plants and significantly increases plant growth and yield of rice in comparison to control treatment. Among the strains, the strain TAN-2 showed maximum efficiency on growth, yield and yield contributing characters of rice followed by the strain TAN-8.
- Genetic diversity analysis by DNA fingerprint analysis showed four different groups of rhizobia in faba nodules. Among the strains, faba-20, faba- 21 and faba-22 are more diverse than other strains. Taxonomic status analysis by housekeeping gene analysis showed that the strains are belonging to the species Rhizobium binae.

# PROGRAM AREA I: GENETIC ENGINEERING AND TISSUE CULTURE 

## 1. TRANSFER OF SALINITY AND DROUGHT TOLERANT GENES INTO RICE THROUGH AGROBACTERIUM MEDIATED GENE TRANSFORMATION

Most of the indica rice genotypes, the world's most cultivated rice types, still remain less amenable to genetic modifications due to their poor regeneration potential (Hiei Y and Komari T, 2008). The existing protocols for transformation and regeneration of indica rice are tedious, lengthy, and highly genotype-specific with low efficiency of transformation. Considering the significance of genetic transformation in functional genomics and crop improvement the need of the hour is to develop an easy, rapid, reproducible, widely applicable and highly efficient transformation and regeneration protocol for various indica rice genotypes which does not necessitate further genotype specific standardization (Khirod K Sahool et al., 2011). In the present study, we have followed a highly efficient and reproducible A. tumefaciens mediated transformation protocol using mature seeds as explants.

Experiments were conducted to establish efficient gene transformation protocol for rice and to find effective method for Agrobacterium mediated transformation for developing transgenic rice variety with enhanced salt tolerance. Here, we used one gene like OsCAL (Calmodulin like protein1) and embrygenic calli of two rice genotypes (IR64 and Kasalath). The basis of selection for these two genotypes callus producing ability is higher. Mature embryo to induce rice callus used as an explants for gene transformation.

## Induction of embryogenic calli from mature embryo

Mature, healthy and diseased free dehusked rice seeds were firstly wash three to five times with sterile distilled water and then sterilized with $70 \%$ ethanol (v/v) for 1 followed by 15 minute $50 \%(\mathrm{v} / \mathrm{v})$ commercial bleach including 2 to 3 drooped of tween 20 with shaking at 180 rpm . Seeds were then washed $8-10$ times with sterile distilled water and dried on autoclaved whatman paper ( 3 mm ) for five minutes. For callus induction twelve to thirteen seeds were incubated per petridis on callus induction medium (MCI) and incubated at $27 \pm$ $1^{\circ} \mathrm{C}$ in dark. MCI was prepared using basal MS medium (Duchefa Biochemie) containing all vitamins supplemented with $30 \mathrm{~g}^{-1}$ sucrose, $0.3 \mathrm{~g}^{-1}$ casein hydrolysate, $0.6 \mathrm{~g}^{-1} \mathrm{~L}$-proline, $3.0 \mathrm{mg}^{-}$ ${ }^{1}$ 2,4-dichlorophenoxyacetic acid (2,4-D), $0.25 \mathrm{mg}^{-1} 6$-benzylaminopurine (BAP), gelled with $6.0 \mathrm{~g}^{-1}$ gelrite and pH adjusted to 5.8 before autoclaving. After 14-21 days of in dark nonembrygenic calli were discarded and only embryogenic calli were selected. These embryogenic calli subcultured again onto fresh MCI and kept for 4 days (dark, $27 \pm 1^{\circ} \mathrm{C}$ ) before transformation with Agrobacterium tumefaciens.

## Bacterial strain and plant expression vector construction

Agrobacterium tumefaciens strain GV3101 harboring OsCAL gene was used for rice transformation. The expression of the genes of interest was under the control of the double constitutive CaMV 35S promoter. The plant expression vector pB2WG7 incorporated the genes of interest OsCAL and Bar gene for selection. The engineering strain was grown in 50 ml of YEM medium, containing $50 \mathrm{mgl}^{-1}$ streptomycin and $50 \mathrm{mgl}^{-1}$ rifampicin in a $28^{0} \mathrm{C}$ shaker at 200 rpm for 16 h . The bacterial suspension was centrifuged and the bacteria was resuspended in the MS re-suspended medium to optical density $\left(\mathrm{OD}_{600}\right)$ of 0.6 to 1.0 , and used for bacterial infection.

## Co-cultivation and selection of transformed calli

The 4 days subcultured embryogenic calli were collected and Agrobacterium infected by immersing them in the Agrobacterium culture (GV3101) for $20-25 \mathrm{~min}$ with intermittent
gentle shaking at 50 rpm . The Agro infected calli were dried on sterile Whatman No. 3 filter paper for 5 min . Calli were then transferred to the co-cultivation medium (MCCM)-MCI containing $10 \mathrm{~g} / 1$ glucose, $\mathrm{pH} 5.2,150 \mu \mathrm{M}$ acetosyringone and incubated at $27 \pm 1^{\circ} \mathrm{C}$ in the dark for around 48 hours. Once slight growth of Agrobacterium appeared around most of the calli. The calli were rinsed $8-10$ times with $250 \mathrm{mg} / \mathrm{l}$ cefotaxime in sterile distilled water, dried
on
sterile Whatman No. 3 filter paper and transferred onto first selection medium-MSM (MCI containing $250 \mathrm{mg} / \mathrm{l}$ cefotaxime) and incubated for 12 days at $27 \pm 1^{\circ} \mathrm{C}$ in dark. After the first selection, brown or black calli were removed and only creamish healthy calli were shifted to the fresh MSM media for second selection and maintained at $27 \pm 1^{\circ} \mathrm{C}$ in dark. After second selection for 10 days, microcalli could be observed which were finally transferred to fresh MSM media for third selection and allowed to proliferate for 5 days at $27 \pm 1^{\circ} \mathrm{C}$ in dark.

## Regeneration of transformed calli

After third selection, black or brown microcalli were discarded and only granular 'macrocalli' were transferred onto regeneration medium containing either two or three growth regulators comprised of MS salts, $30 \mathrm{gl}^{-1}$ maltose, $2 \mathrm{mgl}^{-1}$ kinetin, $0.2 \mathrm{mgl}^{-1}$ naphthalene acetic acid (NAA), pH 5.8 ; gelled with $6.0 \mathrm{gl}^{-1}$ and $250 \mathrm{mgl}^{-1}$ cefotaxime added after autoclaving. These microcalli were incubated at $27 \pm 1^{\circ} \mathrm{C}$ in dark for 7 days for the first phase of regeneration. During the second phase of regeneration, these were shifted to fresh regeneration medium and incubated in light for 4 days. For development of roots, the regenerated shoots were shifted to test tube ( 100 ml ) containing rooting medium MROM (comprising half strength MS salts, $30 \mathrm{gl}^{-1}$ sucrose, $3.0 \mathrm{gl}^{-1}$ phytagel, pH 5.8 and cefotaxime $250 \mathrm{mgl}^{-1}$

We have used seeds as the explants, as these would be available to the researchers all round the year. Seed was plating on MS medium and after 14 days old calli for further subculturing, only the embryogenic calli were subcultured for 4 days on freshly prepared MSmedium. The table table 1) reveled that callus induction and embryogenic callus induction were found higher Kasalath ( 64.66 and $62.32 \%$ ) followed by IR64 ( 56.99 and 50.33\%). After 4 days, only embryogenic calli were subcultured subjected to Agro-infection using Agrobacterium carrying the gene construct and co-cultivated for $\sim 48$ hours on co-cultivation medium. Once the growth ofAgrobacterium could be visualized at the periphery of the individual calli, these were shifted to1 ${ }^{\text {st }}$ selection medium. After $\sim 12$ days on the selection medium, some of the calli turned brownish while the other remained creamish. The creamish colored calli were then transferred tofreshly selection medium for a second selection cycle where small microcalli started growing on the mother calli. These microcalli were gently separated from the mother calli and transferred to fresh MS selection medium for the third selection. During the research period a number of embryogenic calli were infected by OsCAL gene through agrobacterium mediated gene transformation. The research work has been done several of time. Unfortunately the transformed calli were shown bacterial over growth in some of time selection and some of time regenerated stage. This work is going on and optimization will be needed for control the bacterial over growth for infected transformed calli.

Table 1: Varietal differences in percent of callus induction and embryogenic callus of two tested genotypes

| Genotypes | No. of Seed <br> plating | Average \% of callus <br> induction $\pm$ SE | Average \% of embryogenic <br> callus $\pm$ SE |
| :--- | :---: | :---: | :---: |
| IR 64 | 100 | $56.99 \pm 4.20$ | $50.33 \pm 4.56$ |
| Kasalath | 100 | $64.66 \pm 5.66$ | $62.32 \pm 2.93$ |
| CV (\%) | - | 19.29 | 19.38 |
| LSD (0.05) |  | 6.29 | 6.58 |

Fig 1: Steps of Genetic transformation (Oryza sativa L.)
This speedy, yet less labor-intensive, protocol overcomes major limitations associated with genetic manipulation in rice. Moreover, this protocol uses mature seeds as the explants, which can easily be obtained in quantity throughout the year and kept viable for a long time. Such an easy, efficient and generalized protocol has the potential to be a major tool for crop improvement and gene-function studies on the model monocot plant rice.

## 2. PRODUCTION OF DOUBLED HAPLOIDS LINE THROUGH ANTHERS CULTURE FROM RICE F $\mathbf{F}_{1}$ HYBRIDS

In vitro androgenesis or anther culture is a where the pollen grains are made to switch from their normal pollen developmental pathway towards an embryogenic route. It is also a tool for the rapid recovery of fixed breeding lines in rice. Haploid and doubled haploid produced through androgenesis have been used in plant breeding for quite a long time as it can shorten the breeding cycle, fix agronomic characters in homozygous state and increase the selection efficiency of useful recessive agronomic traits.

A total of six $\mathrm{F}_{1}$ populations were grown during the research period in biotechnology research field under optimum management. Out of this two populations (Binadhan-12 x Kasalat and Binadhan-17 x Oryza rufipogon) were at T. aman, 2021 and four populations (BRRIdhan50 x Kasalat, BRRIdhan50 x Pokkali, BRRIdhan50 x Oryza rufipogon and BRRIdhan48xPokkali) were at Boro, 2021-22 season. Boots with appropriate stage (uninucliate/mid uninucleate at reduction division stages) were collected from $\mathrm{F}_{1}$ plants. The boots were pre-incubated in a refrigerator at $8^{\circ} \mathrm{C}$ for $8-10$ days. The panicles were opened from the boots and cut into small pieces. They were then surface sterilized by immersing in $70 \%$ ethanol for 2-3 minutes and then placed onto the sterile filter paper in Petri dishes to remove access alcohol. For callus induction, anthers were incubated in three different culture media (Nitsch, Chu N6, and

Gresshoff \& Doy Medium, Duchefa) and kept in an incubator under dark condition at $25^{\circ} \mathrm{C}$ until callus initiation and subsequent growth up to appropriate size ( 2.0 mm ). Calli were then transferred into regeneration medium (MS medium containing $1.0 \mathrm{mg} / \mathrm{l} \mathrm{NAA}+1.0 \mathrm{mg} / \mathrm{Kn}$ ) and cultures were incubated in a cultured room under cool white fluorescent lamps (approximately 1000 lux, at $25^{\circ} \mathrm{C}$ ) for regeneration. Eight weeks after transfer of calli into the regeneration medium, data were taken on number of anther plated, number of callus produced, number of green and albino plant regenerated.
In T. aman 2021 a total of 16,985 anthers were plated three different type's media from two $\mathrm{F}_{1}$ generations. Out of this only 5 calli $\mathrm{M}_{1}$ medium and 15 Calli $\mathrm{M}_{2}$ medium were found from one $F_{1}$ generation (Binadhan- $12 \times$ Kasalath). Finally only 8 green plant and 6 albino plant were survived which calli were produced from $\mathrm{M}_{1}$ medium (Nitsch and Nitsch). Seed were collected from green plant. Next season harvested seed were tested for further generation improvement.

On the other hand In Boro 2021-22 a total of 10,441 anthers were plated three different types of media from three $\mathrm{F}_{1}$ generations. During the reporting period about 15 calli were count. Out of this only 7 calli was found from $\mathrm{M}_{1}$ medium, 5 calli were found from $\mathrm{M}_{2}$ medium and 3 calli from M3 medium. The research work is ongoing.

Fig 2 : Steps of Anther culture (anther plating to diploid plant)
In conclusion, this method for anther culture was developed and optimized to produce DH lines for an elite F1 hybrid Binadhan- $12 \times$ Kasalat using M2 medium. In this study, a total of eight promising lines were further advanced for on station trial which could be released as varieties, if shows consistent performance in the grain yield and others positive desired characters.

## 3. DEVELOPMENT OF LODGING RESISTANCE AND HIGH YIELD PREMIUM QUALITY RICE VARIETY THROUGH IRRADIATION ON EMBRYOGENIC CALLUS

Tissue culture techniques offer the great possibilities for selection of mutants through the use of new and expanded genetic variability. The variability in the population leads the chance of effective selection and increase the scope of improvement (khanduja and Goel, 1986). Induced mutagenesis serves a source of variability for better selection. Many researchers have attempted to exploit somaclonal variation for crop improvement particularly treated with gamma radiation. Considerable work has been done on induced mutation in rice callus applied low dosage treatment of gamma rays to callus in rice. The present study was under taken to investigate the extent of variability on callus production and plant regeneration of Kataribhog rice cultivar at different dosages of gamma radiation.

Rice (Oryza sative) cv. Kataribhog seed collected from Chrirbondar Upazila Dinajpur . Mature and healthy seeds of this cultivar were dehusked and surface sterilized in $70 \%$ ethanol for 2 minutes followed by 3 times rinses in autoclaved distilled water. Then add $6 \%$ commercial bleach supplemented with 8 drops of Tween 20 (Sigma-Aldrich) per liter. After five rinses using sterilized water then dried about 15 minutes in a sterile petridish with tissue paper. Sterilized and dried seed then cultured in MS medium (Murashige and Skoog, 1962, with including vitamins, Duchefa, Netherlands) with $2.5 \mathrm{mgl}^{-1} 2,4-\mathrm{D}, 30.0 \mathrm{gl}^{-1}$ sucrose and $6.0 \%$ gelrite to initiate the callus. After 14-20 days calli were observed and irradiated three different types of doses gama rays ( 6,8 and 10 GY ). Then only the post embryogenic irradiated calli were transferred to the MS medium supplement with $1.0 \mathrm{mgl}^{-1}$ NAA and 10 $\mathrm{mgl}^{-1}$ Kiniten. Repeated sub culturing was done at an interval of 15 days proliferation and organogenesis. When shoots were initiate after 2-3 weeks about 3-4 cm in height, they were separated aseptically from each other and transfer to freshly prepared rooting medium (Half
strength of MS $+0.55 \mathrm{mgl}^{-1} \mathrm{IBA}$ ). The regenerated test tube containing plantlets were incubated in a controlled growth room at $25 \pm 2^{\circ} \mathrm{C}$ and data were recorded to note the response.

In August 2021 to March 2022 an experiment was conducted Biotechnology division, BINA for knowing the ability of embryogenic callus induction and the effect of irradiation on embryogenic calli of Kataribhog rice cultivar and subsequent regeneration of plantlet from irradiated embryogenic calli. Experiments were performed to observe the effect of gamma rays $(0,6,8$ and 10 Gy ) on embryogenic calli followed by in vitro shoot and root formation in MS medium supplemented with different plant growth regulators. Several parameters such as seed germination percentage, callus initiation, shoot induction and root induction was studied. After callus formation, the calli were treated with different doses of gamma rays ( 0 , $6,8,10 \mathrm{~Gy}$ ) to observe its effect on in vitro regeneration. Data revealed that gamma rays negatively affect both shoot and root regeneration ability of embryogenic callus. Shoot regeneration ability was gradually decreased with the increased doses of gamma rays. Shoot regeneration ability ( $55 \%$ ) was higher at control ( 0 Gy ) condition followed by $37 \%$ at 6 Gy , $25 \%$ at 8 Gy and $15 \%$ at 10 Gy (table 4). The lowest percentage of shoot regeneration was obtained at 10 Gy dose. In root induction, the highest root induction ability ( $68 \%$ ) was observed at control condition followed by 6Gy (66\%), 8Gy (60\%) and 10 Gy ( $50 \%$ ). Like shoot regeneration 6 Gy gamma ray showed better root induction. Finally we got nineteen irradiated in vitro regenerated plantlets out of this 10 plants was $6 \mathrm{~Gy}, 6$ plants was 8 Gy and 3 plants was 10 Gays irradiated embryogenic calli. The established regenerated plant hardening and transferred to the pot containing fertile soil. The experiment will be continuing next year for precise results.

Table 4 : Number of calli irradiation and regenerated plant of Different doses of gamma rays.

| Cultivar | Dose <br> $(\mathrm{Gy})$ | Calli <br> irradiated <br> $($ No) | Irradiated <br> calli sub <br> culture (No) | Survived calli on <br> shooting media <br> (No. \&\%) | Regenerated plant <br> from irradiated calli <br> $($ No. \&\%) |

Fig 3: Steps of Irradiated Calli to new Somaclonal plant development
The results of this study revealed that 6 and 8 Gy of gamma ray might be considered as LD50 for this cultivar.

## 4. DEVELOPMENT OF DROUGHT TOLERANT RICE VARIETY THROUGH PLOYETHYLENE GLYCOL (PEG) STRESSING ON EMBRYOGENIC CALLI OF RICE

Drought is one of the major abiotic stresses causing severe yield loss in crop plants worldwide. In the South and South East Asia, drought causes up to $40 \%$ yield loss. In Bangladesh, this loss ranges from 37-73\% depending on the grain development stage. Screening drought tolerant plants is a way to sustain production under drought environment. However, screening in field is laborious, time consuming and is dependent on resources such as worker, field and power. In vitro selection method could be used as it is simple, ideal and effective for screening large set of germplasms. PEG ( 6000 MW ) has been used in in vitro screening of plants such as rice against drought stress. The present study was conducted to determine the effect of artificial drought stress created by PEG ( 6000 MW ) on callus derived shoot regeneration of two drought tolerant varieties, Binadhan-17 and Binadhan-19.

Seeds of two rice cultivars viz. Binadhan-17 and Binadhan-19 were collected from Plant Breeding Division, Bangladesh Institute of Nuclear Agriculture (BINA), Mymensingh. Mature and healthy seeds of that cultivar were dehusked and surface sterilized in $70 \%$ ethanol for 2 minutes followed by 3 times rinses in autoclaved distilled water. Then add $6 \%$ commercial bleach supplemented with 8 drops of Tween 20 (Sigma-Aldrich) per liter. After five rinses using sterilized water then dried about 15 minutes in a sterile Petridis with tissue paper. Sterilized and dried seed then cultured in MS mesium (Murashige and Skoog, 1962, with including vitamins, Duchefa, Netherlands) with $2.5 \mathrm{mg}^{-1} 2,4-\mathrm{D}, 30 \mathrm{mg}^{-1}$ sucrose and $6 \%$ gelrite to initiate the callus. After 14-20 days to test the calli survivability, 1L of MS medium supplemented with NAA $1.0 \mathrm{mg}^{-1}$, BAP \& Kinetin Concentration at $2.0 \mathrm{mgl}^{-1}$, different concentrations of (PEG) (6000) ( $0 \%, 5 \%, 8 \%, 10 \%$ ) were added. Cultures were maintained at $(25 \pm 2)^{\circ} \mathrm{C}$ temperature under dark condition. The same experiment was carried out three replications. The data of callus induction, percentage of embryogenic callus induction, percentage of shoot and root regeneration and finally percentage of established plant was recorded.

The rice cultivars (Binadhan-19 and Binadhan-17) were cultured in MS medium supplemented with different concentrations and combinations of plant growth regulators. Under dark condition the average percentage of embryogenic callus induction was obtained in the cultivar from Binadhan-19 (60.45\%) which was significantly different from Binadhan17 (50.20\%).

To induce drought stress, different concentrations of PEG ( $0 \%, 5 \%, 8 \%$ and $10 \%$ ) were added in the culture medium. After 14 days, it was clearly observed that the extent of regeneration ability varied from different PEG concentration. In the two cultivars, regeneration percentage was found higher in $0 \%$ concentration. Growth rate and regeneration capacity were decreased with increasing levels of PEG concentration. Among the different concentrations of PEG, The lowest value was recorded for the concentration of $10 \%$ PEG between the cultivars Binadhan-17 (32\%) and Binadhan-19 (40\%) respectively (table 5). At $5 \%$ PEG, the highest value $48 \%$ was recorded in Binadhan-17 and $64 \%$ in Binadhan- 19 . Waniet al. (2010) showed both reduced callus induction and shoot regeneration of rice cultivars PAU 201 and PR116 in medium supplement with different concentrations of PEG. Tripathy (2015) also found similar reduction in regeneration frequency with increased concentration of PEG in upland rice. Further, cultivar depended responses with PEG have also been observed. Akteet al. (2016) found that rice cultivar Binadhan-10 performed the best against PEG compared to Binadhan-4, Binadhan-5, Binadhan-6 and Iratom-24.In this study, under difference PEG levels Binadhan-19 performed better than Binadhan-17. Shoot regeneration and root induction was higher in Binadhan-19 than Binadhan-17. Both the cultivars show reduction in callus induction with increased levels of PEG.

Table 5. Effect of different concentration of PEG (\%) in MS Medium Supplemented with NAA $1.0 \mathrm{mgl}^{-1}$ BAP \& Kinetin Concentration at $2.0 \mathrm{mgl}^{-1}$ on shoot regeneration ability.

| Cultivars | PEG (\%) | No. of calli <br> inoculated | No. of calli showing shoot <br> initiation | Shoot <br> regeneration \% |
| :---: | :---: | :---: | :---: | :---: |
| Binadhan-17 | 0 | 25 | 19 | 76 |
|  | 5 | 25 | 12 | 48 |
|  | 8 | 25 | 10 | 40 |
|  | 10 | 25 | 8 | 32 |
| Binadhan-19 | 0 | 25 | 20 | 80 |
|  | 5 | 25 | 16 | 64 |
|  | 8 | 25 | 14 | 56 |
|  | 10 | 25 | 10 | 40 |

Half strength of MS media with supplemented with different concentration of PEG $(0 \%, 5 \%$, $8 \%$ and $10 \%$ ) were used to see the rooting response of the regenerated shoots. MS medium supplemented with different concentrations of PEG and no growth regulator hormones was found most effective for root induction. The lowest value was recorded for the concentration of $10 \%$ PEG between the cultivars Binadhan-17 (20\%) and Binadhan-19 (30\%) respectively. The highest value at 5\% PEG was recorded in Binadhan-17 (50\%) and Binadhan-19 (60\%) respectively.

The small plantlets which attained good shoot development and produced sufficient roots were transfer to pots containing $50 \%$ soilrite (1:1:1 ratio of vermiculite, perlite and Sphagnum moss) mixed with soil for hardening. Excess agar around the roots was washed off by tap water to prevent microbial infection. Then the pots were kept in a humidity chamber
for $3-5$ days in the culture room under 16 h light and 8 h dark cycle at $28^{\circ} \mathrm{C}$ and then in green house at $(28 \pm 2)^{\circ} \mathrm{C}$. When the plants grew up to a height of above 10 cm and sufficient roots were proliferated, those were transferred to the earthen pot. The tillering capacity and survival rate of the plants in the pots was satisfactory. Finally we got 7 PEG stressing regenerated plant and seed were collected for further evaluation.

Crop genetic improvement for drought stress at the molecular and physiological level is very complex and challenging. The results of this study indicate that, the two rice varieties Binadhan-17 and Binadhan-19 have good callus induction ability as well as inherent tolerance to drought. We suggest that, in vitro screening with the induction of chemical drought by using PEG 6000 to modulate drought tolerance would be a feasible strategy to develop drought tolerant lines of rice. The above study will be the base line for future screening experiments.

## 5. IN VITRO CHEMICAL MUTAGENESIS (EMS) ON RICE CALLI FOR GENETIC VARIATION

Plant growth regulators were used to test callus induction and in vitro regeneration in rice genotype BRRIdhan89. The objectives of the present study were to evaluate a rice genotype for callus induction and regeneration and examined the possible mutations that may occur due to exposure to mutagens. Four different concentrations ( $1,2,3$ and $4 \mathrm{mg} / \mathrm{L}$ ) of 2,4-D for callus induction and three different concentrations ( 1,2 and $3 \mathrm{mg} / \mathrm{L}$ ) of NAA with three doses ( 5,10 and $15 \mu / \mathrm{L}$ ) of kinetin for callus regeneration were evaluated. Several EMS concentrations $(0.05,0.10,0.15,0.20,0.25,0.30,0.35$ and 0.40$) \%$ for 120 min was exposed to induce genetic variation. This study found a high callus induction on MS medium enriched with $2 \mathrm{mg} / \mathrm{L} 2$, 4-D. The half-lethal dosage $\left(\mathrm{LD}_{50}\right)$ of EMS was $0.226 \%$ over the duration of 120 minutes. In the regeneration, it was found that an MS medium enriched with $2 \mathrm{~g} / \mathrm{L}$ Kinetin and $10 \mu \mathrm{~m} / \mathrm{L}$ NAA has the ability to induce higher regeneration of BRRIdhan-89 rice variety. From the regenerated plants, eight plants obtained from $0.2 \%$ EMS for 120 min were availed to complete its life cycle.

Callus induction: In vitro callus induction was investigated using mature BRRIdhan-89 embryos by Using media supplemented with various concentrations of 2,4-D (1.0, 2.0, 3.0, and $4.0 \mathrm{mg} / \mathrm{L}$ ) and without $2,4-\mathrm{D}$ as a control. Different $2,4-\mathrm{D}$ doses have significantly different callus-induction potential (in percent). The callus induction efficiency of BRRIdhan-89 varied from 56 to $85 \%$ for various 2, 4-D concentrations. (Fig 1). Without any 2, 4-D treatment, the control did not induce any callus development. At $T_{2}(2 \mathrm{mg} / \mathrm{L} 2,4-\mathrm{D}$ ), BRRIdhan- 89 had the maximum callus induction ability ( $85 \%$ ) and $T_{3}(2 \mathrm{mg} / \mathrm{L} 2,4-\mathrm{D})$ and $\mathrm{T}_{4}$

Fig 4: Callus induction of BRRIdhan89 rice from mature embryo.
( $2 \mathrm{mg} / \mathrm{L} 2,4-\mathrm{D}$ ) come next.
When the 2,4-D concentration exceeded $2.0 \mathrm{mg} / \mathrm{L}$, it was shown that the frequency of callus induction were reduced. It was observed that different 2,4-D concentrations resulted in

Fig 5: Callus induction percentage of different 2,4-D concentration.
different callus shapes. When 2,4-D levels were high ( 3 and $4.0 \mathrm{mg} / \mathrm{L}$ ), calli were yellowish, short or compact, and crumbly. Calli was produced on MS medium with 1.0 and $2.0 \mathrm{mg} / \mathrm{L}$ of supplements. 2, 4-D was globular in form and creamy to yellowish.

It has been observed that somatic embryogenesis, which produces embryogenic calli from rice scutellum, benefits from medium optimization as well as from the type and concentration of plant growth regulators. It was observed that interactions between genotypes and culture conditions have an impact on the quantity and quality of embryogenic calli. The most effective auxin for callus induction in rice tissue culture, according to several research, is plant growth regulator 2, 4-D. In this work, callus induction from dehusked seeds of six rice genotypes was tested using varying doses of 2, 4-D alone. Different 2, 4-D concentrations

Fig 6: Effect of different doses of EMS for 120 minutes on the callus of BRRIdhan-89.
were shown to result in different callus morphologies. The current study demonstrated that the presence of $2 \mathrm{mg} / \mathrm{L} 2$, 4-D improved callus induction and exhibited varying callus percentages for BRRIdhan-89. This result was consistent with earlier studies that suggested applying 2, 4-D successfully induced calluses in Indica rice. According to Pandey et al. (1994), Thadavong et al. (2002), and Abeyaratne et al. (2004), the ideal concentration of 2, 4D for inducing callus from ripe rice seeds was $2.0 \mathrm{mg} / \mathrm{L}$. The results of the current investigation were consistent with these findings. Additionally, calli generated on semi-solid

MS medium supplemented with $2.0 \mathrm{mg} / \mathrm{L}$ 2, 4-D provided the best desirable traits based on the rice genotypes BRRIdhan-89 [22].

Determination of $\mathrm{LD}_{50} \%$ : The calli were exposed to various concentrations of EMS for 120 minutes, including $0,0.05,0.1,5.25,0.35,0.35,0.35$, and $0.4 \%$. Only $0.05,0.1,0.15,0.2$, $0.25,0.3,0.35$, and $0.4 \%$ EMS were used for subsequence mutation. The half-lethal dose ( $\mathrm{LD}_{50}$ ) of EMS was 0.226 \% of 120 minutes was observed (Fig 1). The calli's proportion of

Fig 7: Effect of EMS on survival rate percentage in callus survival.

Fig 8: Callus regeneration percentage of different 2,4-D concentration.
survival dropped as EMS concentration rose. The survival rate of the untreated EMS callus was above $90 \%$, whereas the survival rate of the callus at $0.4 \%$ EMS was the lowest (Fig 2). According to Datta et al. (2005), the $\mathrm{LD}_{50}$ of each plant varies depending on the explant, the explant age, and the amount of mutagen present.

Regeneration: Calli produced on MS media supplemented with $2.0 \mathrm{mg} / \mathrm{L}$ 2, 4-D were assessed for their plant regeneration ability after application of EMS mutagen. Significant differences were recorded for plant regeneration ability at different kinetin ( $0,1,2$ and 3 $\mathrm{mL} / \mathrm{L}$ ) and NAA ( $0,5,10$ and $15 \mu \mathrm{~g} / \mathrm{L}$ ) concentrations (Table 2). All treatments were found to be significant in the regeneration of plants rather than control. T5 ( $10 \mu / \mathrm{L} N A A+2 \mathrm{mg} / \mathrm{L}$ Kinetin) was observed to have the highest regeneration ability. For plant regeneration, the
ideal concentration of NAA in combination with $2.0 \mathrm{mg} / \mathrm{L}$ kinetin was $10 \mu \mathrm{~g} / \mathrm{L}$, which

Fig 9: Plantlets of BRRIdhan-89 obtained from $0.2 \%$ of EMS treatment.
resulted in the maximum plant regeneration frequency, producing both shoots and roots.
The findings of the present study also revealed that as NAA concentrations increased, the frequency of callus-producing shoots and roots reduced. This could be owing to the high concentration of NAA $(15 \mu \mathrm{~g} / \mathrm{L})$, which could restrict growth and morphogenesis by inhibiting cytokinin accumulation. The effect of varying NAA concentrations in conjunction with kinetin on root production was the polar opposite of the effect on shoot production. With an increment in NAA concentration, the average number of roots generated per callus was increased. As the concentration of NAA in the medium rises, the ratio of auxin to cytokinin rises as well, resulting in improved root regeneration. Thadavong et. al. 2002, described a similar phenomenon. The number of roots generated was reduced when the NAA concentration exceeded $10 \mu \mathrm{~g} / \mathrm{L}$. This NAA severely inhibited growth and morphogenesis at this dose.

Acclimatization: The in vitro grown shoots were green and healthy, and they were moved for acclimation (100 percent vermiculate) and kept at a growth chamber at $25^{\circ} \mathrm{C}, 16 \mathrm{~h}$ photoperiod, and $30-40 \mathrm{~mol} / \mathrm{m} 2 \mathrm{~s}$ cool white fluorescent light, with about 75 percent survival. The roots sprouted and grew nicely within 3 weeks. After being transferred to large pots and grown in a shaded area for two weeks and then in normal conditions. During acclimatization, rooted shoots grew actively and showed no stress symptoms or morphological abnormalities.

Table 6. Yield and yield contributing character of eight mutant derived from $\mathbf{0 . 2 \%}$ EMS for $\mathbf{1 2 0}$ minutes.

| SL | Name of the mutant | Plant <br> Height | Total <br> Tiller | Effective <br> Tiller | Panicle <br> length | Yield per <br> plant (g) |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 1 | EM-89-0.2-1-T1 | 104.2 | 26 | 19 | 26.6 | 49 |
| 2 | EM-89-0.2-2-T1 | 100.8 | 40 | 39 | 26.8 | 110 |
| 3 | EM-89-0.2-3-T1 | 98.4 | 41 | 37 | 25 | 97 |
| 4 | EM-89-0.2-4-T1 | 102.2 | 47 | 42 | 25.8 | 115 |
| 5 | EM-89-0.2-5-T1 | 119.4 | 31 | 31 | 28.4 | 83 |
| 6 | EM-89-0.2-6-T1 | 103 | 32 | 30 | 29.4 | 85 |
| 7 | EM-89-0.2-7-T1 | 118.6 | 18 | 18 | 31.2 | 53 |
| 8 | EM-89-0.2-8-T1 | 113.4 | 19 | 19 | 29.4 | 45 |

The regeneration of the genotype of BRRIdhan-89 was successful. We found eight plants from $0.2 \%$ EMS treated calli those could successfully complete their life cycle. The mutant EM-89-0.2-7-T1 showed the maximum plant height, whereas the mutant EM-89-0.2-3-T

Fig 10: Acclimatization of Plantlets and Plantlets grown in Field condition.
showed the lowest plant height. The mutant EM-89-0.2-4-T1 produced the most effective tiller. Between 45 g and 115 g of yield per plant were produced. The highest yield per plant was obtained by the mutant EM-89-0.2-4-T1.

The MS medium supplemented with $2.0 \mathrm{mg} / \mathrm{L} 2$, 4-D produced the maximum frequency of callus induction from matured embryo for the genotype BRRIdhan89, according to the current study. The half-lethal dosage (LD50) of EMS was $0.226 \%$ over the duration of 120
minutes. The maximum effective concentration of NAA was $10 \mu \mathrm{~g} / \mathrm{L}$ in combination with 2.0 $\mathrm{mg} / \mathrm{L}$ kinetin for plant regeneration. Eight regenerated mutants of BRRIdhan-89 obtained from $0.2 \%$ EMS yielded per plant ranges from 45 g to 115 g . The genetic variation will be verified with other experiments.

## 6. MORPHOLOGICAL AND BIOCHEMICAL EVALUATION OF SOME SELECTED TOMATO SOMACLONES UNDER FIELD CONDITION

## Morphological evaluation of tomato somaclones

Twenty somaclones from three tomato cultivars with their parents were grown in the field and different morphological characters were evaluated. Mean value of plant height (cm), number of leaves, number of branch, number of cluster per plant, number of fruits per plant, single fruit wt.(g) and yield per plant were presented in Table 13. From the results it is revealed that some somaclones exceeded their parents in one or more characters, while significant decrease was also found.

Among the somaclones and their parents, highest plant height ( 90.67 cm ) was found in SC-3 of BARI Tomato 19 which is statistically similar with parent of BARI Tomato $19(90.33 \mathrm{~cm})$. Lowest plant height observed in SC-5 ( 71.17 cm ) of Binatomato-11. For the mean value of plant height, most of the somaclones of Binatomato -12 showed superiority compared with their parent except SC-1, SC-6 and SC-10 which mean value decrease with their parent. In case of Binatomato-11, only mean value of SC-4 ( 74.33 cm ) was lowest compare to parent and all other somaclones value increases over their parents. In BARI Tomato 19, SC-3 and parent showed similar result but all other somaclones mean value decreases. Maximum number of leaves (231) was observed in SC-3 of BARI Tomato 19 which is statistically similar with parent of BARI Tomato 19 (220). Minimum number of leaves was found in SC1 and SC-6 (130) of Binatomato-12. Compare to parent of Binatomato-12 SC-2, SC-4 and SC-8 recorded highest mean value but other somaclones recorded lowest mean value. In Binatomato-11 only SC-1 showed highest mean value (158.67) over their parent. Similar results also observed in BARI tomato 19, only SC-3 showed highest value over the parent The highest mean values of no. of branch per plant were observed in SC-2 of BARI Tomato 19 and parent of BARI Tomato 19 (13). Minimum number of leaves was found in SC-5(5.33) of Binatomato-11. All somaclones except SC-3, SC-4, SC-8 and SC-10 showed superiority over the parent of Binatomato-12. SC-1 and SC-3 of Binatomato-11 also showed superiority over their parents. In BARI Tomato 19, SC-2 and parent showed similar result but all other somaclones mean value decreases.

Maximum cluster per plant ( $17.67,17.5,17.1$ ) were found in SC-4 of BARI Tomato 19 , Binatomato-11 and SC-2 of Binatomato-12. Minimum cluster per plant (7.33, 7.5, 7.5) were observed in SC-3, SC-4 and SC-5 of Binatomato-12. From these findings some somaclones showed superiority compared their parents. Highest fruits per plant (44.33) were found in parent of Binatomato-11 which is statistically similar with SC-2 (42.67) and SC-4 (41.67) of Binatomato-12 and Binatomato-11. Lowest fruits per plant (21.17, 21.67, and 21.67) observed in SC-5, SC-6 of Binatomato-12 and SC-3 of BARI Tomato 19. Highest mean values of single fruit wt. (79.32) were recorded in SC-3 of BARI Tomato-19 which is superior to parent of all cultivars. On the other hand, lowest single fruit wt. (25.55) was recorded in SC-4 of Binatomato-11. Maximum yield per plant (1869.4 g) found in SC-2 of Binatomato-12 which is statistically similar with SC-7 (1611.7 g), SC-9 (1639.5 g) of Binatomato-12. Minimum yield per plant ( 779.7 g ) was found in SC-5 of Binatomato-11.

Table 7. Morphological data of different tomato varieties with their somaclones

The result of correlation coefficient among the different characters was determined by using pearson's coefficient (Table 14). Number of leaves, plant height and branch per plant were positively correlated with each other. Plant height and number of leaves were highly significant and number of leaves with branch per plant showed strong significant positive correlation. Number of fruits per plant and single fruit weight were significantly correlated with yield per plant. Number of cluster per plant was highly significant with number of fruits per plant.

## Biochemical evaluation of tomato somaclones

Some biochemical parameters total soluble solid (TSS), Vit-c, titrable acidity were presented in Table 7. From the data it is found that some somaclones exceeded their parents in one or more characters, while significant decrease was also found.

TSS is a key determinant of shelf life and quality of the crop. Furthermore, TSS levels also contribute strongly to the tomato flavor and consistency (Stevens et al., 1997). TSS ranged from 4.7to $7.2 \%$ (Table 15). The SC-2 of Binatomato-12 gave highest TSS (\%) value (7.2\%) which is statistically similar with SC-3 and SC-4 of BARI Tomato19 (7.1\%, 7.1\%). The lowest TSS (\%) observed in SC-4(4.7\%) of Binatomato-12. SC-3, SC-5, SC-6 and SC-8 mean value of TSS were ( $6.0,6.8,6.7,6.2$ ) which value were superior compare to their parent of Binatomato-12. In Binatomato-11, SC-1 and SC-3 were superior to their parent. In BARI Tomato-19, all somaclones except SC-1 showed highest TSS (\%) value over their parent.

There were significant differences in the amount of ascorbic acid in the different somaclones with their parent of tomatoes studied; it ranges between $17.42 \mathrm{mg} / 100 \mathrm{~g}$ to $25.68 \mathrm{mg} / 100 \mathrm{~g}$ (Table 15). Highest Vit-c content ( $25.68 \mathrm{mg} / 100 \mathrm{gm}$ ) was obtained from SC-2 of Binatomato11which is statistically similar with SC-8 of Binatomato-12 and lowest Vit-c content (17.42 $\mathrm{mg} / 100 \mathrm{gm}$ ) was obtained from SC-4 of Binatomato- 12 . The level of acidity in tomato fruits is an important parameter associated with sensory attributes like flavor and astringency. Titrable acidity varied significantly between 0.38 to 1.13 per cent (Table 15).The highest TA value (1.13) was recorded in SC-3 of Binatomato-11 and lowest value was obtained from SC3 and SC-4 (0.38) of Binatomato-12. The observations recorded for pH are presented in table 15. The pH ranged from 3.62 to 4.36 under different somaclones and their parents. The highest pH value (4.36) was recorded in SC-4 of Binatomato-12 and lowest value was obtained from SC-8 (3.62) of Binatomato-12.

## 7. FUNCTIONAL STUDIES OF OSNHX2 TRANSGENIC TOMATO LINES UNDER SALINITY STRESS

## In vitro salinity study

Three OsNHX2 transgenic lines with wild type plants (BARI Tomato 19) of one (1) week seedlings were grown in MS medium containing 0,100 and 200 mM NaCl . After one (1) month total fresh weight (g/plant) was taken from all plants. All the transgenic lines showed better growth than the wild type plants. Transgenic lines had significantly ( $\mathrm{p}<0.05$ ) higher fresh weight in stress conditions compared with wild type plants.

Fig. 11: Effect of in vitro salt stress on fresh weight (g/plant) of OsNHX2 transgenic lines T1, T2 and T3 along with wild type (WT) plants grown in MS medium containing 0,100 and 200 mM NaCl .
Vertical bars represent the SE of the mean for triplicate determinations.

Fig. 12: Effect of shoot and root length (cm) of OsNHX2 transgenic lines T1, T2 and T3 along with wild type (WT) plants grown in hydrophonic culture containing 0,100 and 200 mM NaCl . Vertical bars represent the SE of the mean for triplicate determinations.

Five week old plants both wild type and transgenic plants that were uniform in height were transferred to the hydroponic system with different salt stress condition. After 15 days of salt stress, wild type plants showed higher fresh shoot weight and root weight compared to transgenic plants in control condition. But when salt stress imposed to 100 mM and 150 mM , $\mathrm{T} 1(39.8 \mathrm{~cm}, 31.9 \mathrm{~cm}), \mathrm{T} 2(41.3 \mathrm{~cm}, 23.5 \mathrm{~cm})$ plants showed higher fresh shoot weight and T1 $(11.8 \mathrm{~cm}), \mathrm{T} 2(12.1 \mathrm{~cm}), \mathrm{T} 3(11.4 \mathrm{~cm})$ plants showed higher root weight in 100 mM and T 1
(12.9 cm), T3(11.8 cm) in 150 mM NaCl concentration compared to wild type plants (Fig. 20).

Five week old plants both wild type and transgenic plants that were uniform in height were transferred to the hydroponic system with different salt stress condition. After 15 days of salt stress some morphological data Shoot fresh weight (g), shoot dry weight (g), root fresh weight $(\mathrm{g})$, and root dry weight ( g ) were taken.

Fig.13. Effect of salinity on shoot fresh weight (g), shoot dry weight (g), root fresh weight (g), and root dry weight (g) of OsNHX2-bar transgenic lines with wild type plants at $0,100 \mathrm{mM}$ and 150 mM NaCl stress condition after 15 days of hydrophonic culture. The data shows the mean $\pm$ S.E of three replicates samples and different letters indicate significant difference at $\mathrm{p}<0.05$ (Tukey HSD AllPairwise Comparisons Test).

After 15 days of salt stress fresh shoot weight were observed where WT ( 8.83 g ) and T1 $(7.66 \mathrm{~g})$ showed higher fresh shoot weight in control condition. When salt stress imposed to 100 mM transgenic plants $\mathrm{T} 1(9.3 \mathrm{~g}), \mathrm{T} 2(9.09 \mathrm{~g})$ and 150 mM NaCl concentration only T1 $(7.24 \mathrm{~g})$ showed higher fresh shoot weight compared to wild type plants. In control and 100 mM salt stress condition no significant variation were found in transgenic and wild type plants but high salt stress condition $(150 \mathrm{mM})$ transgenic plant $\mathrm{T} 1(0.88 \mathrm{~g})$ showed significant difference compared to wild type ( 0.43 g ) plants. Like shoot fresh weight, no significant variation observed in root fresh weight in control condition. When salt stress imposed 100 mM and 150 mM all transgenic plants $\mathrm{T} 1(1.43,1.43 \mathrm{~g}), \mathrm{T} 2(1.53,0.69 \mathrm{~g})$ and $\mathrm{T} 3(1.16, .89 \mathrm{~g})$ showed significant difference compared to wild type ( $0.9,0.53 \mathrm{~g}$ ) plants. Highest Root dry weight were observed both in wild type ( 0.15 g ) and $\mathrm{T} 1(0.17 \mathrm{~g})$ transgenic plant in control condition. 100 mM and 150 mM NaCl salt imposed condition all transgenic plants showed higher root dry weight $\mathrm{T} 1(0.18,0.18 \mathrm{~g}), \mathrm{T} 2(0.19, .09 \mathrm{~g}), \mathrm{T} 3(0.13,0.11 \mathrm{~g})$ with the wild type ( $0.09,0.06 \mathrm{~g}$ ) plants.

## Ion estimation ( $\mathrm{Na}^{+}$and $\mathrm{K}^{+}$)

$\mathrm{Na}^{+}$and $\mathrm{K}^{+}$homoestasis is a crucial step in plants for salt tolerance. $\mathrm{K}^{+}$accumulation of transgenic plants were higher compared to wild type in control condition in shoot. But the salt stress at 100 mM all transgenic plants showed lower content of $\mathrm{K}^{+}$in case of shoot and T 1 showed higher $\mathrm{K}^{+}$content at high dose of NaCl stress $(150 \mathrm{mM})$. But in case of root all transgenic plants accumulate high $\mathrm{K}^{+}(\mathrm{ppm})$ compared to wild type plants in all condition ( 0 $\mathrm{mM}, 100 \mathrm{mM}, 150 \mathrm{mM}$ ) (Fig. $22 \mathrm{~A}, \mathrm{~B}$ ). $\mathrm{Na}^{+}$accumulation (ppm) was similar in both transgenic and wild type plant in control condition in shoot and root. After salt stress at 100 mM and 150 mM all transgenic plants retained higher $\mathrm{Na}^{+}$content (ppm) in than the wild type both in shoot and root (Fig. 22 C,D)

Fig.14: Analysis of $\mathrm{K}^{+}$in shoot (A), root (B) and $\mathrm{Na}^{+}$in shoot (C), root (D) content of OsNHX2-bar transgenic lines with wild type plants at $0,100 \mathrm{mM}$ and 150 mM NaCl stress condition after 15 days of hydrophonic culture. The data shows the mean $\pm$ S.E of three replicates samples.

## Chlorophyll measurement

Five weeks old transgenic (T1, T2, T3) and wild type plants that were uniform in height were transferred to the hydroponic system with nutrient solution. After one week, NaCl salt with two concentrations ( 100 mM and 150 mM ) was added with nutrient solution and also control condition (no salt added) was maintained. After 15 days leaf chlorophyll content were taken using chlorophyll SPAD meter (OPTI-Sciences CCM-200 plus). In control condition no significant difference were observed both of transgenic and wild type plant. Increasing salt stress decreasing the chlorophyll content but the rate of decreasing was less compare to wild type. T1 ( 30.07, and 21.30) and T3 ( $31.87,26.63$ ) plants showed higher value at control, 100 mM and 150 mM concentration (Fig. 23).

Fig.15: Chlorophyll content in leaves of wild type plants (WT) and transgenic (T1, T2, T3) tomato plants overexpressing OsNHX2 under control $(0 \mathrm{mM} \mathrm{NaCl})$ and salt ( $100 \mathrm{mM}, 150$ $\mathrm{mM} \mathrm{NaCl})$ treatments for 15 days hydrophonic culture. The data shows the mean $\pm \mathrm{S} . \mathrm{E}$ of three replicates samples and different letters indicate significant difference at $\mathrm{p}<0.05$ (Tukey HSD All-Pairwise Comparisons Test).

## 8. TRANSFER OF OsNHX2/OsHKT8 GENES INTO ELITE RAPESEED CULTIVARS THROUGH Agrobacterium MEDIATED TRANSFORMATION

OsNHX2 and OsHKT8 high Sodium Potassium ion antiporter gene. Some saline resistance transgenic rapeseed lines will be develope from this research. Rapeseed/ mustard is one of the important crop in Bangladesh. Salinity affects growth and yield attributes of rapeseed. In Bangladesh, more than $30 \%$ of the cultivable land is in the coastal area. Out of about 1.689 million hectares of coastal land 1.056 million hectares are affected by various degrees of soil salinity. After harvesting aman rice, a vast area of land remains unused. There is possibility of bringing this vast fallow saline land under cultivation with salt tolerant rapeseed/mustard varieties in rabi season. High saline resistance variety increase mustard production.

For Transfer of OsNHX2/OsHKT8 genes into elite rapeseed cultivars through Agrobacterium mediated transformation, to establish as in in vitro regeneration protocol is required. The
experiment was set up at tissue culture laboratory, Biotechnology Division, BINA, Mymensingh. In this study, four rapeseed varieties were used i.e BARI Sharisha 14 and BARI Sharisha 18 from Bangladesh Agricultural Research Institute and other two varieties i.e. Binasharisha-4 and Binasharisha-9 from Bangladesh Institute of Nuclear Agriculture. The seeds of rapeseed varieties were washed with sterilized distilled water. Then the seeds were sterilized with $70 \%$ ethanol for 1 min and washed with sterilized distilled water. Then add $3 \%$ solution of sodium hypochlorite and one drop of tween-20 in a falcon tube and shaking for 45 min . Then the seeds rinsed 5-6 times with sterilized distilled water. After sterilization, seeds were blot dried on sterilized Whatman filter papers and inoculated into the germination medium ( $1 / 2 \mathrm{MS}$ medium) in petri plates. pH of the media was adjusted to 5.8.

For callus and shoot initiation, MS media with different concentration growth regulators were used. Hypocotyl from 6-days-old seedlings were cut. Ten formulation of callus and shoot initiation media were prepared with MS media augmented with various concentrations ( 0.5 , $1.0,1.5,2.0$ and $2.5 \mathrm{mg} / \mathrm{L}$ ) of 6-Benzyl aminopurine; BAP1 (Stock $10 \mathrm{mg} / \mathrm{ml}$ ), ( 0.2 and 0.4 $\mathrm{mg} / \mathrm{L}$ ) of 1-Naphthalene acetic acid (NAA), $0.02 \mathrm{mg} / \mathrm{L}$ of Gibberellic acid $\left(\mathrm{GA}_{3}\right)$ and 1.0 $\mathrm{mg} / \mathrm{L}$ of silver nitrate $\left(\mathrm{AgNO}_{3}\right)$. All media were augmented with $30 \mathrm{mg} / \mathrm{L}$ sucrose and solidified with $4 \mathrm{~g} / \mathrm{L}$ gelrite at pH 5.8 . Each treatment repeated thrice. Different regeneration medium was formulated by augmenting the MS media with different concentration of ( $0.00125,0.00250,0.00375,0.0050,0.00625$ and $0.0075 \mathrm{mg} / \mathrm{L}$ ) BAP2 (Stock $2.5 \mathrm{mg} / \mathrm{ml}$ ), 40 $\mathrm{mg} / \mathrm{L}$ adenine hemisulfate and $500 \mathrm{mg} / \mathrm{L}$ Polyvinyl pyrrolidone (PVP 40,000). All media were augmented with $30 \mathrm{gl}^{-1}$ sucrose and solidified with $4 \mathrm{~g} / \mathrm{L}$ gelrite at pH 5.8 . The elongated shoots were transferred to rooting media containing half strength MS media (hormone free) or augmented with IBA $(1 \mathrm{mg} / \mathrm{L})$. All media were augmented with $30 \mathrm{~g} / \mathrm{L}$ sucrose and solidified with $4 \mathrm{~g} / \mathrm{L}$ gelrite at pH 5.8 . Each treatment replicates ten times.

## Results:

The seeds of all the rapeseed varieties were germinated on $1 / 2$ MS medium. Hypocotyls had swollen after 3-4 days of culture, callus and shoot initiate from the cut edges. The hypocotyls cultured on hormone-free MS medium (control), the callus and shoot initiation was 0.0. Among the combinations tested, the highest number of callus and shoot initiation (8.67) observed on MS medium with $1.0 \mathrm{mg} / \mathrm{L}$ BAP1 $+0.2 \mathrm{mg} / \mathrm{L} \mathrm{NAA}+0.02 \mathrm{mg} / \mathrm{L} \mathrm{GA}_{3}+1.0$ $\mathrm{mg} / \mathrm{L} \mathrm{AgNO}_{3}$ in BARI Sharish 18. The lowest number of callus and shoot initiation (3.0) was found from MS medium with $2.5 \mathrm{mg} / \mathrm{L}$ BAP1+ $0.4 \mathrm{mg} / \mathrm{L} \mathrm{NAA}+0.02 \mathrm{mg} / \mathrm{L} \mathrm{GA}_{3}+1.0$ $\mathrm{mg} / \mathrm{L} \mathrm{AgNO}_{3}$ in Binasharisha-9 and BARI Sharish 14.

The shoot regeneration observed after 30 days from inoculation. Only MS medium without BAP $(2.5 \mathrm{~g} \mathrm{mg} / \mathrm{l})$ do not produce any shoot. The highest (6.67) number of shoot induction was found MS media containing with $0.00125 \mathrm{mg} / \mathrm{L}$ BAP $2+40 \mathrm{mg} / \mathrm{L}$ adenine hemisulfate $+500 \mathrm{mg} / \mathrm{L}$ PVP 40,000 in BARI Sharish 18. The lowest (2.33) number of shoot induction was found from MS media with $0.0075 \mathrm{mg} / \mathrm{L}$ BAP2 $+40 \mathrm{mg} / \mathrm{L}$ adenine hemisulfate $+500 \mathrm{mg} / \mathrm{L}$ PVP 40.000 in BARI Sharisha 14. The highest (7) shoot length (cm) was found in Ms media containing with 0.00125 mg L BAP2 $+40 \mathrm{mg} / \mathrm{L}$ adenine hemisulfate $+500 \mathrm{mg} / \mathrm{L}$ PVP 40,000 in BARI sharisha 14 and Binasharisha-4. The lowest (5.83) shoot length was found in MS media containing with $0.0075 \mathrm{mg} / \mathrm{l} \mathrm{BAP} 2+40 \mathrm{mg} / \mathrm{l}$ adenine hemisulfate $+500 \mathrm{mg} / \mathrm{l}+\mathrm{PVP} 40,000$ in BARI sharisha 14.

The elongated shoots around were transferred to $1 / 2$ MS media with $1 \mathrm{mg} / \mathrm{L}$ IBA and $4 \mathrm{~g} / \mathrm{L}$ gelrite for rooting. After 15-20 days root was developed. The well-rooted plantlets were transferred to pots containing soil and sand and the pots were covered with a polythene bag with pores in it. The plantlets were daily nourished with distilled water.

On the basis of present study it may be concluded that the efficiency of callus and shoot initiation in hypocotyl explant was best achieved in MS medium containing BAP1 $1.0 \mathrm{mg} / \mathrm{L}+$ NAA $0.2 \mathrm{mg} / \mathrm{L}+\mathrm{GA}_{3} 0.02 \mathrm{mg} / \mathrm{L}+\mathrm{AgNO}_{3} 1.0 \mathrm{mg} / \mathrm{L}$. The best shoot regeneration and shoot elongation occurred on MS mediium containg with BAP2 $0.00125 \mathrm{mg} / \mathrm{L}+$ adenine hemisulfate $40 \mathrm{mg} / \mathrm{L}+$ PVP $500 \mathrm{mg} / \mathrm{L}$. The root initiation occurred from elongated shoots on $1 / 2 \mathrm{MS}$ (without hormone) or $1 / 2 \mathrm{MS}+$ IBA ( $1 \mathrm{mg} / \mathrm{L}$ ) rooting medium after $15-18$ days and well-developed root found in 15-20 days. The extensive use of high amount of growth regulators reduced shoot initiation and shoot regeneration. Brassica napus varieties showed good callus and shoot initiation, shoot regeneration and shoot elongation than Brassica campestris.

## 9. PHENOTYPIC STUDY OF SOME SWEET PEPPER (CAPSICUM ANNUM L.) GENOTYPES

Sweet pepper is one of the most important nutritious vegetable and its demand is increasing day by day in Bangladesh indicating need to characterize and assess morphological variability for varietal improvement program. Eleven sweet pepper genotypes (Table 1) from native and exotic sources were characterized for thirty morphological traits using vegetative and reproductive appearances at Bangladesh Institute of Nuclear Agriculture, Mymensingh, Bangladesh from November 2021 to March 2022. Noticeable variation was observed among twenty-three qualitative and seven quantitative traits studied. Twenty-six traits showed undisputable variation among the genotypes. Higher number ( 9 genotypes) of light purple, purple and dark purple color at node indicated high amount of anthocyanin content. Leaf shape is used as genotypes identifier at vegetative stage and three types of leaves were found with dark green color (6 genotypes) that is highly correlates with yield. In case of flower, $100 \%$ white color corolla indicates higher number of fruit set. Entire genotypes exhibited one or more exclusive characters especially fruit shape and color in aspect of Bangladesh which could be used as important breeding materials. Fruit color was observed in various categories at intermediate and mature stage as for instance lemon yellow, orange yellow, orange, red, dark red, red with purple tint etc. as well as higher number of blocky fruit shape ( 6 genotypes) were observed and these are the consumer catching attributes of sweet pepper. A positive Correlation was observed among the traits and genetic distance value ranged from 0.17 to 0.68 among the selected genotypes However, selection of genotypes with desirable morphological characteristics can be used for their exploitation of future research program.

The experiment was carried out in plastic pots. A total of $165(11 \times 15)$ pots were prepared. Each pot size was 10 L and hosted one plant. Seeds were soaked in water for 24 hours in order to facilitate germination and subsequently sown on plastic trays in
lines. Sowing of seeds on the tray was done at a depth of one centimeter for easy emergence. Sowing was done on 17 November 2021. Six to seven days were required to start germination. When the seedlings attained 3 leaf stages, they were transferred under the polyethylene shade covering with fine net to prevent from scorching sunlight as well as unexpected storm or heavy rainfall and insect infestation. The seedlings were watered thoroughly every day as per on the requirement. Thirty days old seedlings were transplanted on 22 December, 2021, in well prepared experimental pots comprising of soil, compost and sand (3:1:1).One teaspoon of urea, half teaspoon of MoP and gypsum were applied 25 and 50 days after transplanting of seedlings in the pots. During the crop cycle, appropriate intercultural operations were performed for proper plant growth and development, such as irrigation at different growth stages, weeding, soil mulching and staking as and when needed. Different types of insect infestation were occurred during the experimental period such as mites, aphids, and yellow strip armyworm. To control these karishma, zero mite and mukti @ $1 \mathrm{ml} / 1 \mathrm{~L}$ of water were sprayed at 7 days interval.

Observations of different characters were recorded from eleven sweet pepper genotypes at specified stages of crop growth period when the characters under study had full expression. Five plants from each genotype were randomly selected and tagged for recording the observations. The data was taken in the form of descriptor codes assigned by IPGRI, AVRDC and CATIE (1995) for the crop capsicum (Capsicum $s p p$.). Fruit parameters were recorded by observing 10 fruits from different plants on mature fruits in the first harvest unless specified. Correlation and dissimilarity study was done by Past 4.10 software.

Plant Growth Characteristics: Diverse variation was found regarding eleven morphological traits of capsicum observed at appropriate stage of each genotype and displayed in Table 2. Two types of stem color were observed such as, dominant green (7 genotypes) and green with purple streak (4 genotypes). Most of the genotypes (10) exhibited cylindrical or round stem shape with strong intensity of anthocyanin coloration i.e., light purple color on nodes ( 5 genotypes) while angled stem shape were found in case of one genotypes as well as equally two genotypes showed green and purple color at nodes. Purple color or purple color streak on chilli plants indicates the presence of high amount of anthocyanin content, which is an effective antioxidant for human body. Plant growth habit was characterized as prostate, intermediate and erect, where intermediate ( 8 genotypes) was found dominant compared to prostate (3 genotypes). The branching habit was intermediate in all the genotypes except one sparse and only two genotypes were dense.

Leaf Characteristics: Leaf shape was mainly lanceolate (5 genotypes); some genotypes had deltoid (3) and ovate (3) shape leaves. In the present investigation dark green leaf color was more ( 6 genotypes) than green ( 4 genotypes) and light green ( 1 genotype) color. The dark green color of leaves is generally due to presence of high chlorophyll content in the leaves which ultimately leads to increased yield. Hence, it becomes a good criterion for selection of elite cultivars group. All the genotypes in the present study had entire leaf margin but leaf pubescence were sparse (4 genotypes), intermediate ( 3 genotypes) and dense (4 genotypes). The leaf density was equally dense ( 5 genotypes) and intermediate ( 5 genotypes) as well as sparse in case of one genotype.

Characterization of Reproductive Plant Parts: The most important advances obtained in the genetic improvement of plants are associated with the knowledge of their reproductive system and thirteen morphological traits of reproductive organ of sweet pepper genotypes are arrayed in Table 3. Flower position highly influences the degree and mode of pollination. All of the germplasm showed intermediate flower position and were found having attractive white corolla color which is a desirable trait as it helps in attracting pollinators during the pollination process. Fruit color of sweet pepper genotypes at different stages is one of the most desirable traits for selecting a suitable inbred line. Attractive fruit color, lesser fruit pubescence and smooth fruit texture are the factors which determine consumer acceptability of the product. Hence, these traits become good selection criterion for a breeder. In the present study it was found that fruit color at intermediate stage was green (8 genotypes) and more prominent than lemon green and deep green. Diversified fruit color was observed at mature stage such as Lemon yellow, Orange yellow, Orange, Red, Dark red and Red with purple tint. Among these, red color (4 genotypes) was more dominant (Table 3). Wider variation was found for fruit shape. As per consumer's preference blocky fruits are more preferable and higher number of blocky fruits were observed (6 genotypes) than triangular (4 genotypes) and elongate (1 genotype) shape. Fruits are categorized into four categories based on fruit shape at blossom end as like sunken (5 genotypes), pointed (3 genotypes), blunt (2 genotypes) as well as sunken and pointed (1 genotype). Fruit shape at pedicel attachment was found obtuse (1 genotype), cordate (3 genotypes) and lobate ( 7 genotypes). Blocky fruit shape, lobate pedicel attachment, sunken blossom end, pendent fruit position and dark green fruit color at maturity are desirable attributes. Perfect fruit shape, size and color along with mild taste are the main quality parameters that make the task of developing new genotypes/variety/hybrids very sticking. All the genotypes were devoid of blossom end fruit appendages except CKN8 and CKN- 11. As most of the genotypes were blocky, so intermediate corrugation (5 genotypes) found dominant over slightly corrugated (4 genotypes) and corrugated (2 genotypes) at cross section. All the genotypes had straw color seed and most of the genotypes (6 genotypes) contained more than fifty ( $>50$ ) seeds which were measured from ten fruits in each replication and the average was considered to the number of seed per fruits.

Correlation among the selected traits of the genotypes: Correlation study indicated that there were a significant positive correlation among fruit length, fruit weight and yield per plant. There were also positive correlation between fruit diameter and fruit weight along with no. of fruit per plant and yield per plant. But plant height had a negative correlation with fruit weight and yield per plant.

Genetic Dissimilarity Analysis: Green colored point showed lowest genetic dissimilar pair while red colored point indicated maximum genetic dissimilarity. In Gower's matrix the genotype CKN-3 was found to be the most dissimilar accession with others followed by CKN11, CKN-12. The genotype CKN-13 showed higher amount of similarity with another genotypes followed by CKN-9, CKN-7 and CKN-6 . In this study, genetic distance among eleven sweet pepper genotypes ranged from 0.17 to 0.68 .

| LSD $_{0.05}$ | 4.72 | 2.97 | 15.71 | 0.89 | 0.97 | 66.306 |

Based on the above discussion it can be concluded that a distinct morphological variation was observed among eleven sweet pepper genotypes. Among different morphological traits studied, a higher frequency was observed for plant height, nodal anthocyanin, dark green leaves, intermediate branching habit and flower position, blocky fruit shape, green and red color fruit, sunken blossom end shape, fruit length and diameter, fruit weight, yield etc. indicating fitness of genotypes. The study suggested that the genotypes like CKN-1, CKN- 2, CKN- 8 and CKN- 9 exhibited desirable characters in various aspects. So, the four genotypes can be selected for the further sequence of the research programs i.e., genetic engineering and tissue culture for higher yield and quality improvement of sweet pepper in Bangladesh.

## PROGRAMME AREA II: MARKER ASSISTED SELECTION/MARKER ASSISTED BACKCROSS BREEDING

## 10. SCREENING OF SOME SELECTED TIDAL TOLERANT RICE LINE

Bangladesh is the largest deltaic country in the world. Its ecology and climatic conditions offer fertile land for agricultural production. However, the land is also vulnerable to water submergence, sea-level rise (SLR) and intense storm surge events. By the year 2030, global climate models estimate that Bangladesh's annual mean temperature will increase by $10^{\circ} \mathrm{C}$, accompanied by a $5 \%$ increase in annual precipitation and a 14 cm rise in sea level.
Farmers in tidal floodplain of Jhalakati and adjoining areas of Pirojpur, Barguna and Patuakhali districts covering substantial area of Southern Delta Region grow traditional aman rice cultivars. Most traditional aman rice cultivars are tall, long duration, and photoperiod-sensitive with low
yield potential. So the study was undertaken to developed suitable advanced line to cultivate in tidal situation have similar plant and better yielding capacity than indigenous rice cultivar through irradiation and other advanced techniques.

In T. aman 2021 for tidal submerged tolerant rice variety development twenty-one $\mathrm{F}_{4}$ lines, seventeen $\mathrm{F}_{3}$ lines and $23 \mathrm{M}_{3}$ mutant lines were planted in BINA head quarter, Mymensingh. In T. Aman 2021, three $\mathrm{F}_{5}$ line were selected from $21 \mathrm{~F}_{4}$ lines from their better performance. A total of $56 \mathrm{~F}_{4}$ plant were selected from $17 \mathrm{~F}_{3}$ lines. The collected samples were bulked and dried, stored for the next season further evaluation. On the other hand, a total of $12 \mathrm{M}_{4}$ mutant lines were selected from $23 \mathrm{M}_{3}$ mutant lines. The selected seeds were collected, dried and stored for further evaluation. Each progeny was grown in a 0.5 m squares meter with line to line distance 20 cm and plant to plant distance 15 cm using single seedling/hill. Fertilizer was applied at 90:15:30:5:2 of NPKSZn $\mathrm{kg} / \mathrm{ha}$ and standard agronomic practices were followed.

## 11. ADVANCE YIELD TRIALS OF SOME SELECTED HIGH YIELDING RICE LINE

Recent studies by several groups have shown that despite its inferior agronomic performance, a wild rice, an accession of Oryza rufipogon, is likely to contain genetic factors that can increase the yield of modern varieties. It was reported that Oryza rufipogon allele at two QTL loci on chromosome 1 and 2 were associated with an 18 and $17 \%$ increase in grain yield per plant, respectively, without delaying maturity or increasing plant height. This discovery suggested the innovative use of wild and exotic germplasm for rice crop improvement through molecular markers. Therefore, the proposed study is set to increase yield of modern Bangladeshi rice varieties through selectively introgressing useful genes from accessions of $O$. rufipogon.

A total of thirteen advance breeding materials were grown in Boro, 2021-22 with three standard checks viz Binadhan-16, BRRI dhan96 and BRRI dhan100. The design of the experiment was RCBD with three replication at BINA head quarter, Mymensingh. Each progeny was grown in a $4.0(2.0 \mathrm{~m} \times 2.0 \mathrm{~m})$ squares meter with line to line distance 20 cm and plant to plant distance 15 cm using single seedling/hill. Fertilizer was applied at 120:25:40:10:4 of NPKSZn kg/ha and standard agronomic practices were followed.

During the Boro, 2021-22 thirteen materials were grown with three standard checks at BINA HQs, Mymensingh. Out of these only six materials (Table--) were selected depending on the duration and comparable yield with the checks for further evaluation. The tested lines and the check differed significantly for grain yield and maturity. The line Bina(bio)-BC2-5-2-3-14 produced the higher yield ( $9.05 \mathrm{t} / \mathrm{ha}$ ) followed by line Bina(bio)-BC2-5-2-11-2-33 (8.82 t/ha) and line Bina(bio)-BC2-5-2-3-50 (8.65 t/ha). The check variety BRRI dhan96 also produced the higher yield and it was 9.0 t/ha. Highest plant height were found line Bina(bio)-BC2-5-2-3-31 ( 151 cm ) followed by line Bina(bio)-BC2-5-2-3-20 (135cm) and the lowest was BRRI dhan96 ( 110 cm ) followed by Bina(bio)-BC2-5-2-3-49 (111cm). The yield of the selected lines other agronomic characters further evaluation is needed. So, next season selected lines will be transplanted in the fields.

Table 16. Average yield and days to maturity of some selected materials in Boro, 2021-22 at BINA HQs, Mymensingh

| Sl. No. | Line Name | Maturity | Plant height | Yield (ton/ha) |
| :---: | :--- | :---: | :---: | :---: |
| 1 | Bina(bio)-BC2-5-2-3-14 | $140-145$ | 112 | $\mathbf{9 . 0 5}$ |

| 14 | Binadhan-16 | $150-153$ | 113 | 7.77 |
| 15 | BRRI dhan96 | $140-145$ | 110 | 9.00 |
| 16 | BRRI dhan100 | $148-150$ | 112 | 7.1 |
|  |  |  |  |  |

## 12. SCREENING OF SOME SELECTED SALT TOLERANT HIGH YIELDING RICE LINE

Salinity is one of the major obstacles to increasing production in rice growing areas worldwide. Therefore, development of salt tolerant varieties has been considered as one of the strategies to increase rice production in saline prone coastal areas. In Bangladesh, out of 2.8 million hectares of the coastal area, around 1.0 million ha has become saline due to heavy withdrawal of surface and groundwater for irrigation and intrusion of seawater. The total coastal saline area covers one third of the 9 million hectares of total cultivated area in Bangladesh. Thus, the objective of this study was to identify salt tolerant rice genotypes using molecular markers and to introgress saltol gene from IR4630 into BRRI dhan28 with marker assisted selection technique.

This experiment was carried out to select desirable lines or plants having high yield with salt tolerant. A total of five advance breeding materials were grown in Boro, 2021-22 with one standard checks viz BRRI dhan 28 . The size of unit plots was $2.0 \mathrm{~m} \times 2.0 \mathrm{~m}$. Plant to plant distance was 15 cm and row to row distance was 20 cm using single seedling $/$ hill. The experiment followed RCBD with three replications. On the other hand, a total of $92 \mathrm{~F}_{3}$ lines were grown during the season for selecting better lines or plant selection. Fertilizer was applied at 120:25:40:10:4 of NPKSZn kg/ha and standard agronomic practices were followed.

The following table revealed the mean data of three replication of the advanced yield trial. Among the tested lines and compared with check three advanced lines were selected for further evaluation. The highest yield were found Bina(bio)-Sl-bc2-5-2-4-15 (8.67 t/ha) line followed by Bina(bio)-Sl-bc2-5-2-5-17 (7.30 t/ha) and Bina(bio)-Sl-bc2-5-2-1-11 (7.06 t/ha) line. The highest plant height were found line Bina(bio)-Sl-bc2-5-2-5-17 (124cm) followed by Bina(bio)-Sl-bc2-5-2-3-6 (123cm) and the lowest was BRRIdhan28 ( 105 cm ).

Table 17. Agronomic characteristics of selected materials tested as advanced yield trial, Boro, 2021-22

| Sl. No. | Line Name | Maturity | Plant height | Yield |
| :---: | :--- | :---: | :---: | :---: |
| 1 | Bina(bio)-Sl-bc2-5-2-3-6 | $145-146$ | 123 | 6.17 |
| 2 | Bina(bio)-Sl-bc2-5-2-2-9 | $145-146$ | 109 | 6.47 |

## 13. DEVELOPMENT OF LODGING RESISTANCE AND HIGH YIELD PREMIUM QUALITY RICE VARIETY THROUGH MARKER ASSISTED SELECTION

Aromatic or scented rice have long been highly regarded in our society not only because of their excellent quality but also because they had been considered auspicious. The aromatic rice variety Kataribhog in the district of Dinajpur, are medium long type, fine grained and highly scented. The cultivar is highly priced in the locality where they are grown. These varieties are characterized by weak stem, highly lodging tendency, very long growth duration, low grain weight and poor yield. Binadhan-13 is another aromatic rice variety in our country, but the variety same problem. Farmers mainly grow these varieties for their own consumption and ceremonial purposes. Under this circumstance a program were taken the two aromatic varieties improved as yield potential and lodging resistance through hybridization with oryza rufipogon and BR5.

This experiment was carried out to select desirable lines or plants having high yield with fine grains and aroma. A total of $38 \mathrm{~F}_{2}$ materials (Binadhan-13x BR5) were grown in T. aman, 2021. On the other hand, Twenty five $\mathrm{F}_{3}$ (Kataribhog x Oryza rufipogon) lines were grown in Boro 2021-22. The size of unit plots was $0.50 \mathrm{~m} \times 1.0 \mathrm{~m}$. Plant to plant distance was 15 cm and row to row distance was 20 cm using single seedling/hill. Fertilizer was applied at 120:25:40:10:4 of NPKSZn kg/ha and standard agronomic practices were followed.

In T. aman 2021 about $100 \mathrm{~F}_{3}$ plants were selected from 25 segregating $\mathrm{F}_{3}$ populations. Sub sequentially population improvement the previous materials were grown in Boro, 2021-22 and twenty nine $\mathrm{F}_{4}$ (Kataribhog x Oryza rufipogon) lines/plants were selected on the basis of better plant types compare to the parents. On the other hand $107 \mathrm{~F}_{3}$ plants/lines were selected in T . aman 2021 from the 38 (Binadhan-13x BR5) $\mathrm{F}_{2}$ populations. The seeds of selected plants were harvested and store for the next season further evaluation.

## PROGRAMME AREA III: MICROBIAL BIOTECHNOLOGY

## 14. COMPERISON OF THE EFFECTIVENESS OF COMMON BIOFERTILIZERS FOR PEA, LENTIL AND LATHYRUS

Rhizobia, the gram-negative soil bacteria, forms root nodules with legume crops and influences their growth and yield. We evaluated the ability of the selected rhizobial strains to affect the growth and yield of pea, lentil, and lathyrus on the high Ganges River floodplain soils of Bangladesh under field conditions. The field experiment included five treatments- three indigenous rhizobial strains (BL129, BL153, and BL460), one mixed culture, and a control. Pea, lentil, and lathyrus seeds were inoculated with rhizobial strains as per the treatments and planted. In this study, we assessed the growth and production of pea, lentil, and lathyrus in Bangladesh's Gangetic flood plain soils using three native strains (BL129, BL153, and BL460). Inoculation of pea with indigenous strain BL460, inoculation of lentil with strain BL129 and inoculation of lathyrus with strain BL460 recorded higher grain yields than all other treatments. Inoculation of indigenous mixed strains also resulted in significantly higher pea, lentil, and
lathyrus grain yields than control. Thus, indigenous strains BL129 can be used for lentil and BL460 for pea and lathyrus cultivation to improve nodulation, growth and yield of pea, lentil, and lathyrus on the high Ganges River floodplain soils of Bangladesh.

Significant variation was observed for plant height at different treatment but there was no significant variation in case of branch per plant. Maximum plant height was observed for the treatment $T_{4}$ and maximum branch per plant was observed for the treatment $T_{1}$. Maximum hundred seed weight, dry weight per plant and plot yield was observed for the treatment $\mathrm{T}_{3}$ in pea. Significant variation of nodule per plant and nodule weight was observed for different treatment of lentil. For lentil maximum noudule per plant and nodule weight was observed for the treatment $\mathrm{T}_{1}$.

Table 18. Effect of rhizobial strain on growth, yield and yield contributing character of pea

| Treatment | At 50\% flowering stage |  |  | At harvest |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Nodule per plant | Nodule weight (g plant ${ }^{1}$ ) | $\begin{gathered} \text { Dry } \\ \text { weight } \\ \text { per } \\ \text { plant } \end{gathered}$ | Plant height | Branch per plant | Pods per plant | Seed <br> per <br> pod | Hundred seed weight | Plot yield |
| $\begin{gathered} \mathrm{T}_{1} \\ (\mathrm{BL} 129) \\ \mathrm{T}_{2} \end{gathered}$ | 20.07c | 0.0473a | 11.43ab | 160.67a | 3.93a | 37.2b | 5.31a | 10.33a | 960c |
| $\begin{gathered} (\mathrm{BL} 153) \\ \mathrm{T}_{3} \end{gathered}$ | 22.4 b | 0.0636a | 10.71bc | 155.67b | 3.53a | 40.27b | 4.76b | 10.31a | 1243.3a |
| (BL460) | 19.67c | 0.058a | 12.42a | 163.33a | 3.47a | 48.67a | 4.80b | 10.37a | 1276.3a |
| $\begin{aligned} & \mathrm{T}_{4} \text { (BL129, } \\ & \text { BL153 and } \end{aligned}$ |  |  |  |  |  |  |  |  |  |
| $\begin{gathered} \text { BL460) } \\ \mathrm{T}_{5} \end{gathered}$ | 28.13a | 0.0597a | 9.65 c | 163.67a | 3.87a | 34.47b | 4.31c | 9.49b | 1052b |
| (Control) | 15.2d | 0.0536a | 9.7 c | 151.67b | 3.4a | 33.27 b | 3.71d | 9.32 b | 926.3c |
| CV\% | 3.97 | 15.75 | 8.12 | 1.48 | 11.2 | 9.61 | 4.5 | 3.73 | 2.46 |

Significant variation in the yield contributing character of lentils was observed across treatments. For lentil treatment T1, it was observed that maximum pods per plant, hundred seed weight and plot yield were. There was a significant variation in nodule per plant and nodule weight for several treatments in lathyrus. Maximum noudule per plant and nodule weight for lathyrus were observed for treatments $\mathrm{T}_{2}$ and $\mathrm{T}_{3}$.

Table 19. Effect of rhizobial strain on growth, yield and yield contributing character of lentil.

| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

The traits plant height, branch per plant, pods per plant, hundred seed weight, dry weight per plant, and plot yield significantly varied among treatments. For the traits branch per pod, seed per pod, hundred seeds per pod, dry weight per plant and plot yield, $T_{1}$ was the most necessary feature treatment. $T_{3}$ was found to have the highest plant height, seed weight per hundred seeds, and plot yield. Between $T_{1}$ and $T_{3}$, there was no significant difference in the trait plot yield.

The performance of indigenous rhizobial strains was better than mixed strain and control in producing pea, lentil and lathyrus yield. Compared to all other treatments, the inoculation of pea with the native strain BL460, lentil with strain BL129, and lathyrus with strain BL460 resulted in greater grain yields.

## 15. GENETIC DIVERSITY OF FABA BEAN Rhizobia FROM DIFFERENT LOCATION OF BANGLADESH

Faba bean (Vicia faba L) is a protein rich legume crop which enable to fix atmosphereic nitrogen in association with Rhizobim bacteria. This association provides environment friendly substitution of industrial N - fertilizers with associated improvement in resource efficiency and production costs. Twenty five (25) rhizobial strains were isolated from root nodules of faba bean. To understand morpho-physiological characteristics of the isolated strains, they were evaluated by different morpho-physiological tests. Results revealed that colony size of the strains was ranged from 1.2 to 2.00 mm . All strains showed positive result in nodulation test and also showed acid producing fast growing nature in bromothymol blue (blue) test. In salt tolerance test, four strains (faba-1, faba-2, FM-4c and FM-4f) showed better performance at $1.7 \% \mathrm{NaCl}$ and nine strains (Faba -1, Faba -2, Faba -6, Faba -10, FM-1a, FM-4c, BL-129, BL153 and 640) able to grow at PH 5.7. Two strains (faba- 1 and faba-2) able to sustain in high temperature $\left(40^{\circ} \mathrm{C}\right)$ and high phosphate solubilization index was obtained in Faba-2 (2.75). Symbiotic effectiveness of these isolates was evaluated by conducting pot experiment. The highest seed yield ( 7.33 gplant-1) and protein content ( $33.63 \%$ ) were found from inoculation with faba-2 followed by FM- 1a and faba-10. With that in case of all parameters related to growth and yield viz. plant height, chlorophyll content, number of branches plant-1, number of nodules plant1, nodule dry weight, number of pods plant-1, number of seeds pod-1 and 100seed weight Faba-2 showed the best result compared to others. Among the strains $66.67 \%$ strains showed better performance over control-1 (absolute control) while $44.4 \%$ strains showed high performance than control-2 (nitrogenous control) and only $27.74 \%$ showed lower performance due to "cheating behavior" or "selfish character". So, it could be concluded that strain Faba-2, FM-1a and Faba-10 appears as the promising strains to produce bio-fertilizer as the means of restoring soil fertility and reduction of chemical nitrogenous fertilizers in faba bean. Genetic diversity analysis by DNA fingerprint analysis showed four different groups of rhizobia in faba nodules. Among the strains, faba-20, faba- 21 and faba-22 are more diverse than other strains. Taxonomic status analysis by housekeeping gene analysis showed that the strains are belonging to the species Rhizobium binae. Although Rhozbium etli is the main symbiont of faba bean in the rest of the world but in Bangladesh we did not find any strain belong to this species.

Fig 20: DNA fingerprint of rhizobial strains from faba bean nodule.

## 16. EVALUATION OF PLANT GROWTH-PROMOTING RHIZOBACTERIA (PGPR) FOR THE ENHANCEMENT OF RICE GROWTH AND YIELD UNDER POT CONDITION

Plant growth-promoting rhizobacteria (PGPR) are beneficial bacteria that colonize plant roots and enhance plant growth by a wide variety of mechanisms. Therefore, the use of PGPR is steadily increasing in agriculture and offers an attractive way to replace chemical fertilizers. Here, we have isolated the PGPR from the cow dung for the enhancement of growth of rice. Cowdung were collected from different cattle shed/house of Mymensingh, Bangladesh and twenty bacterial strains were selected based on colony morphology. Three bacterial isolates designated as CD1A, CD2A and CD3 were used with $50 \%$ recommended dose of fertilizer in this experiment as treatments to investigate their effects on the growth and yield of rice by pot culture experiment at field condition. Prior to transplantation, seedlings were inoculated with bacterial strains as per treatment. Most of the treatments significantly increased plant height, total tiller per hill, effective tiller per hill, filled grain per panicle and grain weight per plant. Among the treatments, treatments $\mathrm{T}_{1}$ (CD1A $+50 \%$ fertilizer), $\mathrm{T}_{2}\left(\mathrm{CD} 2 \mathrm{~A}+50 \%\right.$ fertilizer) and $\mathrm{T}_{3}$ (CD3+50\% fertilizer) were found better in producing effective tillers per hill, filled grain per panicle and grain yield per plant. The present study, therefore, suggests that the bacterial isolates $\mathrm{CD} 1 \mathrm{~A}, \mathrm{CD} 2 \mathrm{~A}$ and CD3 could be used as bio-fertilizers for reducing the use of chemical fertilizers, enhancing growth and yield of rice at field conditions. Further evaluation is needed for confirm their beneficial effects on rice cultivation.

Isolation of PGPR: Twenty bacterial isolates were successfully isolated from the cow dung. They were designated as CD1A, CD2A and CD3 were used in this experiment.

Days to maturity: Significant difference was observed for the trait days to maturity for different treatments. Early maturity was observed in the treatments $T_{1}, T_{2}, T_{3}$ and $T_{4}$ where $T_{6}$ took maximum days to mature. Both T 8 and control needed more days to mature than the other inoculated treatment.

Plant height: The PGPR isolates significantly affected the height of rice seedlings. Results reveal that plant height increased in bacterial treated plants over uninoculated control. The highest plant height $(92.67 \mathrm{~cm})$ was recorded in $\mathrm{T}_{2}$ followed by $\mathrm{T}_{4}(92 \mathrm{~cm})$ and $\mathrm{T}_{1}(91.67 \mathrm{~cm})$. Phosphorus is one of the major nutrients, second only to nitrogen in requirement for plants. Most of phosphorus in soil is present in the form of insoluble phosphates and cannot be utilized by the plants (Pradhan and Sukla, 2006).

Table 21. Effect of PGPR bacterial strains on growth of rice

| Treatment | Days to <br> maturity <br> (days) | Plant <br> height <br> $(\mathrm{cm})$ | Total <br> tiller per <br> hill | Effective <br> tiller per <br> hill | Panicle <br> length <br> $(\mathrm{cm})$ | Filled grain <br> per panicle | Grain weight <br> per hill (gm) |

| Abb |  |  |  |  |  |  |  |

Abbreviations: $\mathrm{T}_{1}=\left(\mathrm{CD} 1 \mathrm{~A}+50 \%\right.$ fertilizer), $\mathrm{T}_{2}=\left(\mathrm{CD} 2 \mathrm{~A}+50 \%\right.$ fertilizer), $\mathrm{T}_{3}=(\mathrm{CD} 3+50 \%$ fertilizer $)$, $\mathrm{T}_{4}=(\mathrm{MIX}+50 \%$ fertilizer $), \mathrm{T}_{5}=(\mathrm{CD} 1 \mathrm{~A}+100 \%$ fertilizer $), \mathrm{T}_{6}=(C D 2 \mathrm{~A}+100 \%$ fertilizer $), \mathrm{T}_{7}=$ (MIX $+100 \%$ fertilizer), $\mathrm{T}_{8}$ ( $100 \%$ fertilizer) and Control (No fertilizer)

Total tiller per plant: Among the eight treatments, treatment T6 produced the highest tiller per plant followed by T5 but they were statistically non-significant. The ability of bacteria to solubilize mineral phosphates has been of interest to agricultural microbiologists as it can enhance the availability of phosphorus and iron for plant growth. PGPR have been shown to solubilize precipitated phosphates and enhance phosphate availability to rice that represent a possible mechanism of plant growth promotion under field conditions (Verma et al., 2001).

Fig 23: Effect of different PGPR treatment on growth of rice.
Panicle length: For the parameter of panicle length, there was a significant variation across treatments. The greatest panicle length was measured for the treatment $\mathrm{T} 4(25.60 \mathrm{~cm})$ then for T8.

Filled grain per panicle: The grain with the maximum filling was observed in T 1 (156) treatment which was followed by T4 (138.07) and T3 (133.33).

Grain yield per hill: For the various treatments, a significant variance in grain yield per hill was observed. The largest grain yield per hill was observed at the treatment $T_{1}$ followed by $T_{2}$ and $\mathrm{T}_{3}$. The control, which received no fertilizer or bacterial inoculation had the lowest grain production per panicle.

The experimental results suggest that used PGPR bacterial strains can reduce the use of chemical fertilizers, improve the growth and yield of rice plants. There for use of PGPR as bio-fertilizers is an efficient approach to replace chemical fertilizers for sustainable rice cultivation in Bangladesh. Further investigations are needed to clarify the role of these PGPR strains as biofertilizers that exert beneficial effects on plant growth and development.

## 17. EVALUATION OF ARSENIC TOLERENT BACTERIA FOR REDUCTION OF ARSENIC UPTAKE IN RICE IN ARSENIC CONTAMINATED SOIL

The study was undertaken to test the effects of isolated arsenic tolerant bacterial strains from arsenic contaminated areas of Bangladesh on growth and yield of rice. Isolated strains were characterized by morphological, biochemical, functional properties and, identified by 16S-rRNA gene sequencing. Isolated strains were able to grow at higher concentration of arsenic at laboratory conditions. After complete characterization, a pot experiment was conducted during 2021-2022 to scrutinize the role of isolated bacterial strains on rice growth, yield and uptake of arsenic in arsenic contaminated soil. The objective of the present study was to evaluate arsenic tolerant bacteria for reduction of arsenic uptake in rice in arsenic contaminated soil. It was observed that three strains combat the As toxicity in plants and significantly increases plant growth and yield of rice in comparison to control treatment. Among the strains, the strain TAN2 showed maximum efficiency on growth, yield and yield contributing characters of rice followed by the strain TAN-8. Thus, these results clearly show that the strain TAN-2 showing to its intrinsic abilities of rice growth promotion and could be used for phytostabilization of rice in arsenic contaminated soil.

Days to maturity: Arsenic creates adverse condition in rice rhizophere and influence on growth duration of crops. Different treatments showed significant effect on growth duration of rice (Table-1). The maximum growth duration was observed in the control treatment and minimum was in the treatment two. Pots that were not treated with any arsenic tolerant bacteria took longer time to mature.

Plant height: There was no significant effects were observed on plant height due to the application of different treatments (Table-1).

Total tiller per hill: Different treatments showed significant influence for producing tiller per plant (Table-1). Among the treatments, $\mathrm{T}_{1}$ produced the maximum total tiller per hill from a single tiller which was followed by the treatments $T_{2}, T_{3}$, and $T_{4}$. The treatments $T_{2}, T_{3}$, and $T_{4}$ showed significant effects on tiller/hill over the control treatments. Control treatment, $\mathrm{T}_{5}$ produced the lowest total tiller per plants.

Effective tiller per hill: Effective tiller produced by different treatments showed significant variations (Table-1). The treatments $\mathrm{T}_{1}$ showed maximum potentiality for producing effective tiller per hill among the five treatments which was followed by the treatment $T_{2}$. The lowest effective tiller per plant was recorded in control treatment which was statistically similar to the treatment $\mathrm{T}_{4}$.

Panicle length: Panicle length was not significantly influenced by different treatments (Table1). The panicle length was between 23.6 and 24.73 cm among different treatments. Maximum panicle length was observed in treatment $\mathrm{T}_{2}$ and minimum in control treatment.

Filled grain per panicle: Filled grains per panicle produced by different treatments showed significant differences (Table-1). The maximum filled grains found in the treatment T 1 followed by the treatment $T_{2} . \quad T_{1}$ and $T_{2}$ had the most grains per panicle, respectively. The least amount of grain was obtained per panicle in the control group, where no bacterial strain was injected.

Unfilled grain per panicle: The treatment $\mathrm{T}_{5}$ had the most unfilled grains per panicle, followed by $T_{2}$ and $T_{1}$ (Table-1). The lowest number of unfilled grains per panicle was observed in $T_{3}$. Treatments $T_{1}, T_{2}, T_{3}$, and $T_{4}$ showed no significant change for producing unfilled grains per panicle.

Fig 24: Effect of arsenic tolerant bacteria on growth and yield of rice at arsenic contaminated soils

Table 21: Effect of arsenic tolerant bacteria on growth and yield of rice at arsenic contaminated soils

| Treatment | Days to <br> maturity <br> (days) | Plant <br> height <br> $(\mathrm{cm})$ | Total <br> Tiller <br> per hill | Effective <br> tiller per hill | Panicle <br> length <br> $(\mathrm{cm})$ | Filled <br> grain <br> per <br> panicle | Unfilled <br> grain <br> per <br> panicle |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{T}_{1}$ | 131 bc | 84.4 a | 10.53 a | 9.93 a | 24.47 a | 136.6 a | 25.33 b |
| $\mathrm{~T}_{2}$ | 128 c | 81 a | 7.33 ab | 7.6 ab | 24.73 a | 131.4 a | 26.73 b |
| $\mathrm{~T}_{3}$ | 128.33 c | 81.33 a | 8.8 ab | 7.27 b | 24.2 a | 95.8 b | 14.73 b |
| $\mathrm{~T}_{4}$ | 133.33 b | 79.73 a | 8.6 ab | 4.6 c | 23.87 a | 93.87 b | 20.4 b |
| $\mathrm{~T}_{5}$ | 138.67 a | 74.33 a | 6.2 b | 4.33 c | 23.6 a | 43.33 c | 53 a |
| $\mathrm{CV} \%$ | 0.75 | 8.22 | 10.7 | 9.67 | 3.69 | 6.6 | 9.46 |

Treatments details: $\mathrm{T}_{1}$ (TAN-2), $\mathrm{T}_{2}$ (TAN-8), $\mathrm{T}_{3}$ (TAN-10), $\mathrm{T}_{4}$ (MIX=TAN-2, TAN-8, TAN-10) and $\mathrm{T}_{5}$ (Control)

Grain yield per pot: Grain yield was significantly influenced by different treatments The treatment $\mathrm{T}_{1}$ produced maximum yield ( $89 \mathrm{~g} / \mathrm{pot}$ ) which was followed by the treatment $\mathrm{T}_{2 \text {. . the }}$ treatments $T_{3}$ and $T_{4}$ produced statistically similar yield but significantly different over control treatment. The lowest grain yield was found in control treatment.

Chemical analysis: Chemical analysis for arsenic content in rice grain and straw are under process.

Arsenic tolerant strain TAN-2 and TAN-8 could be used as bacterial inoculants for mitigation of arsenic uptake by rice in arsenic contaminated soil. Further experiment is needed for validation of the pot experiment data.

[^0]:    N. B.: In a column, values with same letter(s) for individual location/combined means do not differ significantly at 5\% level.
